## TABLE OF CONTENTS

ACRONYMS AND ABBREVIATIONS .....	VII
1.0 INTRODUCTION.....	1
1.1 Background .....	1
1.2 Inventory Structure .....	2
1.3 Summary of GHG Emissions Results .....	8
2.0 STATIONARY COMBUSTION (SCOPE 1) .....	14
2.1 Buildings .....	14
2.2 Emergency Generators and Fire Pumps .....	16
2.3 Welding Gases .....	18
3.0 MOBILE COMBUSTION (SCOPE 1) .....	19
3.1 Central Automotive Division Fleet .....	19
3.2 PATH Diesel Equipment .....	22
4.0 FUGITIVE EMISSIONS (SCOPE 1) .....	24
4.1 Use of Refrigerants .....	24
4.2 Use of Fire Suppressants.....	26
4.3 Historic Elizabeth Landfill .....	27
5.0 PURCHASED ELECTRICITY (SCOPE 2).....	29
5.1 Buildings.....	29
5.2 Rail Systems.....	32
6.0 PURCHASED STEAM, HEATING, AND COOLING (SCOPE 2).....	33
6.1 KIAC Heating and Cooling.....	33
6.2 Con Edison Steam.....	34
7.0 ENERGY PRODUCTION (SCOPE 3) .....	35
7.1 Kennedy International Airport Cogeneration.....	35
7.2 Essex County Resource Recovery Facility .....	37
8.0 AIRCRAFT (SCOPE 3) .....	39
8.1 Aircraft Movements and Auxiliary Power Units .....	40
8.2 Ground Support Equipment .....	45
9.0 ATTRACTED TRAVEL (SCOPE 3) .....	48
9.1 Airport Passengers .....	48
9.2 Air Cargo .....	55
10.0 MOBILE COMBUSTION (SCOPE 3) .....	58
10.1 Shadow Fleet.....	58
11.0 TENANT ENERGY CONSUMPTION (SCOPE 3) .....	59
11.1 Buildings.....	59
11.2 Rail Systems.....	63
12.0 REFERENCES.....	64
APPENDIX A: SCOPE 3 GHG EMISSIONS BY YEAR OF ASSESSMENT .....	69
APPENDIX B: 2016 OPERATIONS BY AIRCRAFT CODE .....	70
APPENDIX C: 2016 GROUND SUPPORT EQUIPMENT PROFILES .....	80
APPENDIX D: REVISIONS TO THE 2006 BASE YEAR.....	82

TEB	Teterboro Airport
TPY	tons per year of pollutant
VALE	Voluntary Airport Low Emissions Program
VMT	vehicle miles traveled
VOCs	volatile organic compounds
WFC	World Financial Center
WTC	World Trade Center

## **1.0 INTRODUCTION**

### **1.1 BACKGROUND**

The Port Authority of New York and New Jersey (Port Authority) owns, manages, and maintains bridges, tunnels, bus terminals, airports, the Port Authority Trans-Hudson (PATH) commuter rail system, and marine terminals that are critical to the metropolitan New York and New Jersey region's trade and transportation capabilities. Major facilities owned, managed, operated, or maintained by the Port Authority include John F. Kennedy International Airport (JFK), Newark Liberty International Airport (EWR), LaGuardia Airport (LGA), Stewart International Airport (SWF) and Teterboro Airport (TEB); the George Washington Bridge and Bus Station; the Lincoln and Holland tunnels; Port Newark; Howland Hook Marine Terminal; the Port Authority Bus Terminal (PABT); and the 16-acre World Trade Center (WTC) site in lower Manhattan.

In June 1993, the Port Authority issued its environmental policy affirming its long-standing commitment to provide transportation, terminal, and other facilities of commerce within its jurisdiction, to the greatest extent practicable, in an environmentally sound manner and consistent with applicable environmental laws and regulations. On March 27, 2008, the Board of Commissioners expanded the Port Authority's environmental policy to include a sustainability component that explicitly addresses the problem of climate change and ensures that the agency maintains an aggressive posture in its efforts to reduce greenhouse gas (GHG) emissions. The cornerstone of this policy is the dual goal of (a) reducing GHG emissions related to its facilities, including tenants and customers, by 80 percent from 2006 levels by 2050; and (b) pursuing a net zero GHG emissions goal for its operations (Port Authority 2008).

The Port Authority retained the services of SC&A, Inc. to conduct annual emission inventories covering GHGs and co-pollutants that are collectively referred to as criteria air pollutants (CAP). The Port Authority's inventories follow international best practices for defining the inventory boundary in terms of an organizational and operational boundary, and further characterizing the operational boundary in terms of scope 1, scope 2, and scope 3 emissions (WRI 2004). A thorough discussion of the Port Authority's inventory structure is provided in Section 1.2.

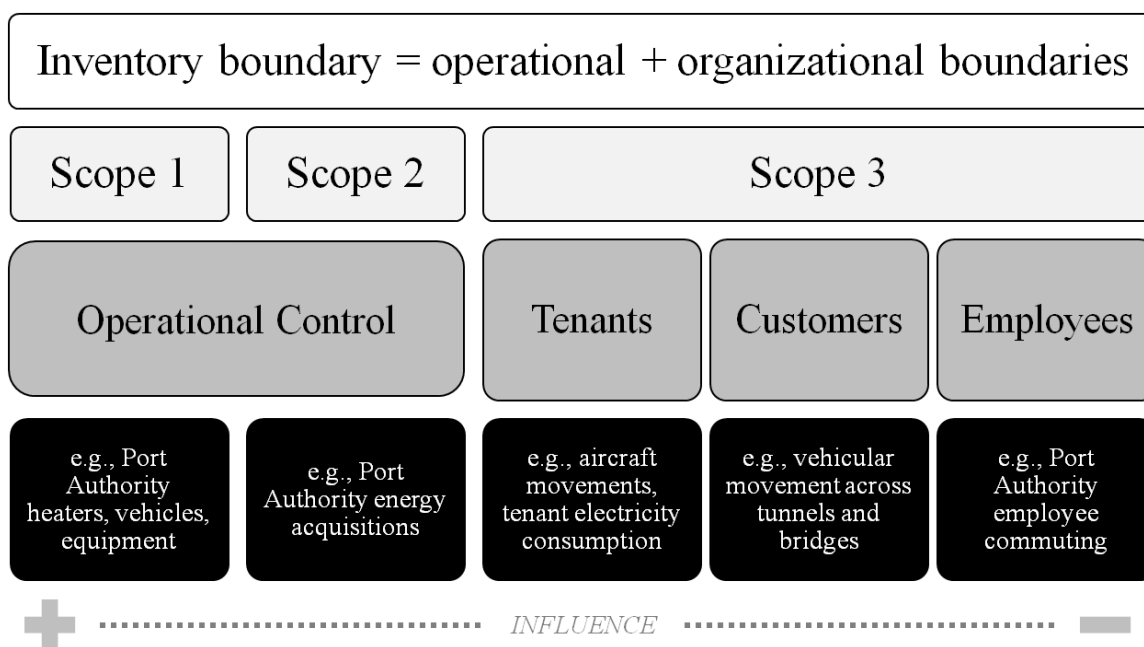

The Port Authority is publishing this 2016 GHG and CAP inventory as a tool for evaluating the effects of ongoing mitigation actions and informing the design of future environmental and sustainability initiatives.

## 1.2 INVENTORY STRUCTURE

The structure of the Port Authority's GHG and CAP inventory conforms to the corporate accounting and reporting standard (GHG Protocol) published by the World Resources Institute and World Business Council for Sustainable Development (WRI 2004). Per the GHG Protocol, the Port Authority defined the inventory boundary in relation to its organizational and operational boundaries. The Port Authority sets the organizational boundary using the operational control approach. The GHG Protocol defines operational control as an organization "[having] the full authority to introduce and implement its operating policies at the operation" (WRI 2004). The Port Authority's operational boundary encompasses direct and indirect emissions as follows:

- Direct Scope 1 emissions resulting from the combustion of fuels by or fugitive losses from sources operated by the Port Authority (e.g., Port Authority owned and controlled vehicles, air conditioning equipment, and emergency generators).
- Indirect Scope 2 emissions pertain to Port Authority energy acquisitions for the benefit of its operations but from sources not operated by the Port Authority (e.g., electricity purchases for the benefit of Port Authority operations).
- Indirect Scope 3 emissions relate to emissions from tenant and customer activities within or physically interacting with Port Authority owned facilities (e.g., aircraft movements during landing and take-off cycle below an altitude of 3,000 feet (ACRP 2009)), vehicular movements across bridges and tunnels). This scope also includes emissions from Port Authority employee commuting.

To clarify the extent to which the Port Authority has influence over scopes 1, 2, and 3 emitting activities, a carbon management dimension was added to the inventory boundary. At one end of the carbon management spectrum are activities over which the Port Authority has the most influence, such as energy acquisitions for the benefit of its own operations (e.g., natural gas, transportation fuels, electricity purchases). At the other end, there are activities over which the Port Authority has little influence, such as an employee's decision on mobility (e.g., use of personal vehicle versus mass transit for daily commuting). An illustration of the Port Authority's inventory boundary and key structural features is shown in Figure 1-1.

**Figure 1-1. Schematic of the Port Authority's Inventory Boundary**

### 1.2.1 Pollutant Coverage

The Port Authority inventory covers the six main GHGs: carbon dioxide (CO<sub>2</sub>), methane (CH<sub>4</sub>), nitrous oxide (N<sub>2</sub>O), hydrofluorocarbons (HFCs), perfluorocarbons (PFCs), and sulfur hexafluoride (SF<sub>6</sub>). Where applicable, the report also shows emissions in CO<sub>2</sub>e, where the emissions of each pollutant are multiplied by their respective global warming potential (discussed in Section Global Warming Potentials) to express total radiative forcing effects in a single unit, with CO<sub>2</sub> as the reference gas. The inventory also quantifies key co-pollutants referred to collectively as criteria pollutants or CAPs; these include nitrogen oxides (NO<sub>x</sub>), sulfur oxides (SO<sub>x</sub>), particulate matter with an aerodynamic diameter of 10 microns or less (PM<sub>10</sub>), and particulate matter with an aerodynamic diameter of 2.5 microns or less (PM<sub>2.5</sub>).

### 1.2.2 Global Warming Potentials

The Intergovernmental Panel on Climate Change (IPCC) developed global warming potentials (GWPs) to quantify the globally averaged relative radiative forcing effects of a given GHG, using CO<sub>2</sub> as the reference gas. In 1996, the IPCC published a set of GWPs in its Second Assessment Report (IPCC 1996). In 2001, the IPCC published its Third Assessment Report (IPCC 2001), which adjusted the GWPs to reflect new information on atmospheric lifetimes and an improved calculation of the radiative forcing of CO<sub>2</sub>. The IPCC adjusted these GWPs again during 2007 in its Fourth Assessment Report (IPCC 2007). However, Second Assessment Report GWPs are still used by international convention to maintain consistency with international practices, including by the United States and Canada when reporting under the United Nations Framework Convention on Climate Change. GWP values from the Second Assessment Report were used and are presented in Table 1-1.

<b>Table 1-1: Global Warming Potential Factors for Reportable GHGs</b>			
<b>Common Name</b>	<b>Formula</b>	<b>Chemical Name</b>	<b>GWP</b>
Carbon dioxide	CO <sub>2</sub>	N/A	1
Methane	CH <sub>4</sub>	N/A	21
Nitrous oxide	N <sub>2</sub> O	N/A	310
Sulfur hexafluoride	SF <sub>6</sub>	N/A	23,900
<b>Hydrofluorocarbons (HFCs)</b>			
HFC-23	CHF <sub>3</sub>	trifluoromethane	11,700
HFC-32	CH <sub>2</sub> F <sub>2</sub>	difluoromethane	650
HFC-41	CH <sub>3</sub> F	fluoromethane	150
HFC-43-10mee	C <sub>5</sub> H <sub>2</sub> F <sub>10</sub>	1,1,1,2,3,4,4,5,5,5-decafluoropentane	1,300
HFC-125	C <sub>2</sub> H <sub>2</sub> F <sub>5</sub>	pentafluoroethane	2,800
HFC-134	C <sub>2</sub> H <sub>2</sub> F <sub>4</sub>	1,1,2,2-tetrafluoroethane	1,000
HFC134a	C <sub>2</sub> H <sub>2</sub> F <sub>4</sub>	1,1,1,2-tetrafluoroethane	1,300
HFC-143	C <sub>2</sub> H <sub>3</sub> F <sub>3</sub>	1,1,2-trifluoroethane	300
HFC-143a	C <sub>2</sub> H <sub>3</sub> F <sub>3</sub>	1,1,1-trifluoroethane	3,800
HFC-152	C <sub>2</sub> H <sub>4</sub> F <sub>2</sub>	1,2-difluoroethane	43
HFC-152a	C <sub>2</sub> H <sub>4</sub> F <sub>2</sub>	1,1-difluoroethane	140
HFC-161	C <sub>2</sub> H <sub>5</sub> F	fluoroethane	12
HFC-227ea	C <sub>3</sub> H <sub>2</sub> F <sub>7</sub>	1,1,1,2,3,3,3-heptafluoropropane	2,900
HFC-236cb	C <sub>3</sub> H <sub>2</sub> F <sub>6</sub>	1,1,1,2,2,3-hexafluoropropane	1,300
HFC-236ea	C <sub>3</sub> H <sub>2</sub> F <sub>6</sub>	1,1,1,2,3,3-hexafluoropropane	1,200
HFC-236fa	C <sub>3</sub> H <sub>2</sub> F <sub>6</sub>	1,1,1,3,3,3-hexafluoropropane	6,300
HFC-245ca	C <sub>3</sub> H <sub>3</sub> F <sub>5</sub>	1,1,2,2,3-pentafluoropropane	560
HFC-245fa	C <sub>3</sub> H <sub>3</sub> F <sub>5</sub>	1,1,1,3,3-pentafluoropropane	950
HFC-365mfc	C <sub>4</sub> H <sub>3</sub> F <sub>5</sub>	1,1,1,3,3-pentafluoropropane	890
<b>Perfluorocarbons (PFCs)</b>			
Perfluoromethane	CF <sub>4</sub>	tetrafluoromethane	6,500
Perfluoroethane	C <sub>2</sub> F <sub>6</sub>	hexafluoroethane	9,200
Perfluoropropane	C <sub>3</sub> F <sub>8</sub>	octafluoropropane	7,000
Perfluorobutane	C <sub>4</sub> F <sub>10</sub>	decafluorobutane	7,000
Perfluorocyclobutane	c-C <sub>4</sub> F <sub>8</sub>	octafluorocyclobutane	8,700
Perfluoropentane	C <sub>5</sub> F <sub>12</sub>	dodecafluoropentane	7,500
Perfluorohexane	C <sub>6</sub> F <sub>14</sub>	tetradecafluorohexane	7,400

### 1.2.3 Operational Control Emissions

Emissions that fall under the operational control of the Port Authority include direct scope 1 emissions and indirect scope 2 emissions as defined by the GHG Protocol (WRI 2004). The Port Authority sponsors annual assessments of scope 1 and scope 2 emissions for the purpose of tracking progress towards the goal of carbon neutrality for Port Authority operations. To that end, the Port Authority selects emission estimation methods that meet a materiality standard of 5 percent (i.e., the sum of errors and misstatements do not exceed 5 percent of total emissions). The Port Authority successfully registered the 2010, 2011, and 2012 scope 1 and scope 2 inventories with TCR. These GHG inventories were independently verified to be complete, transparent, and materially accurate. Since 2015, the Port Authority also voluntarily discloses its verified carbon footprint to CDP, a not-for-profit organization that provides a global system for companies and cities to measure, disclose, manage, and share vital environmental information, and has its GHG inventory independently verified by a third party on an annual basis.

The characterization of emission sources under the operational control of the Port Authority is presented in Table 1-2. Emission sources are grouped by general emission categories, including stationary and mobile combustion; purchased heating, cooling and steam; and fugitive emissions. In addition, a range of activities associated with these emission categories is provided. “Buildings” represents emissions from energy consumption (e.g., natural gas or electricity) at Port Authority facilities. “Emergency Generators and Fire Pumps” corresponds to emissions from fuel combustion by emergency response equipment. “Rail Systems” refers to emissions from energy acquisitions for the operation of the PATH light rail lines and stations. Emissions from combustion of transportation fuels by the Port Authority’s Central Automotive Division fleet broken down by two fleet segments, the “CAD Main Fleet,” and the “Executive Fleet.” Emissions from combustion of fuels for operation of non-road equipment along the PATH system are labeled “PATH Non-Road Equipment.” “Refrigeration/Fire Suppression” refers to unintentional releases of refrigerant from air conditioning equipment and intentional releases from specialty fire suppression systems. “Landfill Gas” is associated with fugitive emissions from a closed landfill on Port Elizabeth. “Welding” refers to emissions that stem from routine maintenance operations.

Table 1-2 also identifies for each emitting activity the corresponding scope and indicates whether biogenic emissions are also generated. For the Port Authority, biogenic emissions are the result of bioethanol and biodiesel fuel consumption by the CAD fleet and CO<sub>2</sub> fugitive emissions from the closed Elizabeth Landfill.

<b>Table 1-2: Characterization of Sources under the Operational Control of the Port Authority</b>				
<b>Emission Category</b>	<b>Activity</b>	<b>Scope</b>		
		<b>1</b>	<b>2</b>	<b>Biogenic</b>
Stationary Combustion	Buildings	✓		
	Emergency Generators and Fire Pumps	✓		
	Welding	✓		
Mobile Combustion	CAD Main Fleet	✓		✓
	Executive Fleet	✓		✓
	PATH Non-Road Equipment	✓		
Purchased Electricity	Buildings		✓	
	Rail Systems		✓	
Purchased Cooling	Buildings		✓	
Purchased Heating	Buildings		✓	
Purchased Steam	Buildings		✓	
Fugitive Emissions	Landfill Gas	✓		✓
	Refrigeration/Fire Suppression	✓		

#### **1.2.4 Scope 3 Emissions - Tenants**

The Port Authority promotes commerce and regional economic development with the help of partners, tenants, and contractors (hereinafter referred to as “tenants”). In general, tenants conduct business within Port Authority facilities (e.g., operation of cargo handling equipment in maritime terminals) or interact directly with Port Authority infrastructure (e.g., aircraft movements). Emissions from tenant activities fall outside the Port Authority’s operational control, and therefore are classified as scope 3. Emission estimates for tenant sources are based on best

available methods and data sources. In some cases, these estimates have a margin of error of less than 5 percent, but in most cases, tenant emission estimates do not subscribe to a 5 percent materiality standard. Assessing tenant emissions helps the Port Authority identify environmental and sustainability initiatives that can best be achieved in collaboration with its tenants.

The characterization of tenant emission sources is presented in Table 1-3. Emission sources are grouped by general emission categories, including stationary and mobile combustion; purchased heating, cooling and steam; and aircrafts. In addition, a range of activities associated with these emission categories is provided. “Buildings” corresponds to emissions from tenant energy consumption (e.g., natural gas or electricity). “Cargo Handling Equipment” points to emissions from fuel combustion by cargo processing equipment at maritime ports. “Ferry Movements” are mobile emissions from ferry operations that arrive to and depart from the Port Authority’s World Financial Center (WFC) terminal. “Rail Locomotive” refers to mobile emissions from such equipment on Port Authority property. “Rail Systems” refers to emissions from energy acquisitions for the AirTrain light rail lines and stations. “Shadow Fleet” corresponds to mobile emissions from vehicles owned by, but not operated by, the Port Authority. “Auto Marine Terminal, Vehicle Movements” are mobile emissions from staging imported vehicles on the premises of the Auto Marine Terminal (AMT). “Non-Road Diesel Engines” reflects emissions from diesel construction equipment activity on Port Authority sponsored sites. “Aircraft Movements” account for emissions from aircraft engines during a landing and take-off cycle. “Auxiliary Power Units” are emissions from aircraft auxiliary engines used to provide lighting and air conditioning at the terminal gate. Finally, “Ground Support Equipment” refers to emissions from equipment used to service aircrafts between flights.

<b>Table 1-3: Characterization of Tenant Sources</b>			
<b>Emission Category</b>	<b>Activity</b>	<b>Scope</b>	
		<b>3</b>	<b>Biogenic</b>
Stationary Combustion	Buildings	✓	
Mobile Combustion	AMT, Vehicle Movements	✓	
	Ferry Movements	✓	
	Rail Locomotives	✓	
	Shadow Fleet	✓	
	Cargo Handling Equipment	✓	✓
Purchased Electricity	Buildings	✓	
	Rail Systems	✓	
Purchased Cooling	Buildings	✓	
	Rail Systems	✓	
Purchased Heating	Buildings	✓	
	Rail Systems	✓	
Construction	Non-Road Diesel Engines	✓	
Aircrafts	Aircraft Movements	✓	
	Auxiliary Power Units	✓	
	Ground Support Equipment	✓	

### 1.2.5 Scope 3 Emissions - Customers

The Port Authority promotes commerce and regional economic development for the benefit of the public (hereinafter referred to as “customers”). Emissions from customer activities fall outside the Port Authority’s operational control and are therefore classified as scope 3. Emission estimates for customer sources are based on best available methods and data sources, but customer emission estimates do not subscribe to a 5 percent materiality standard. Assessing customer emissions helps the Port Authority consider carbon and air pollution impacts stemming from utilization of its infrastructure and may inform decision-makers on the selection and design of future capital projects.

The characterization of customer emission sources is presented in Table 1-4. Emission sources are grouped by general emission categories, including attracted travel and energy production. Attracted travel refers to customer motorized travel to access Port Authority infrastructure and includes a range of activities. The category “Drayage Trucks” covers emissions from drayage trucks moving cargo inland from the maritime ports. “Commercial Marine Vessels” refers to emissions from vessels that call on Port Authority ports. “Airport Passenger” accounts for emissions from motorized travel to access Port Authority air terminals. “Air Cargo” pertains to emissions associated with the distribution of cargo shipping to and from Port Authority airports. “Through Traffic” describes emissions from vehicles that travel across Port Authority tunnels, bridges and bus terminals. “Queued Traffic” accounts for emissions from vehicular congestion when the demand for a given tunnel or bridge exceeds its capacity. “Electricity Sold to Market” accounts for emissions from electricity that is generated in Port Authority-owned power plants but consumed downstream by a non-specified end-user through the electricity market. This category excludes electricity produced in a Port Authority-owned power plant and consumed by the Port Authority or a Port Authority tenant. Note that electricity production at the Essex County Resource Recovery plant is generated primarily from the combustion of municipal solid waste (MSW), which qualifies by federal and New Jersey state law as biogenic emissions. Finally, the “Energy Recovery Program” refers to the distribution of low-cost electricity to local business impacted by the events of September 11<sup>th</sup>, 2001.

### 1.2.6 Scope 3 Emissions - Employees

The Port Authority includes in its scope 3 boundary emissions associated with the commuting of its employees. The Port Authority regularly conducts anonymous employee surveys to collect information about commuting habits, including but not limited to distance, mode, origin and destination. Through these surveys, the Port Authority gathers feedback about proposed initiatives affecting employee commuting. The characterization of employee emission sources is presented in Table 1-5: Characterization of Employee Sources

## 1.3 SUMMARY OF GHG EMISSIONS RESULTS

This section presents the results of the 2016 GHG inventory for anthropogenic emissions, unless otherwise specified. CAP emissions were estimated as co-pollutants and those emissions results are presented thematically at the end of each chapter.

In 2016, the Port Authority had a total carbon footprint (scopes 1+2+3) of 5,909 thousand metric tons CO<sub>2</sub>e. This represents an increase of 1.3 percent relative to the revised 2006 base year<sup>1</sup>. Since 2006, the Port Authority has achieved notable emission reductions in scope 2 emissions through the implementation of energy efficiency and energy conservation initiatives. Additionally, the Port Authority has kept scope 3 emission in check despite growing customer demand for Port Authority infrastructure over time. A comparison of the 2016 carbon footprint with the 2006 baseline is presented in Figure 1-2.

<sup>1</sup> In March 2018, the 2006 base year inventory was revised to reflect the best practices adopted by Port Authority's GHG inventory program. The revisions to the 2006 inventory are detailed in Appendix D of this report.

**Figure 1-2. 2016 GHG Inventory Comparison with the 2006 Baseline**

The carbon footprint of the Port Authority's operations (scopes 1+2) amounted to 234,657 metric tons of CO<sub>2</sub>e in 2016. Since 2006, the Port Authority achieved a reduction of 34,921 metric tons CO<sub>2</sub>e through changes in operations and implementation of numerous sustainability initiatives. This level of carbon mitigation corresponds to a 13 percent reduction relative to the 2006 base year. The goal of achieving carbon neutrality for Port Authority operations is attainable with the help of market instruments and additional operational improvements. Most notably, the Port Authority could mitigate 71 percent of operational control emissions by retiring renewable energy certificates (RECs) against 456,658.5 MWh consumed. An additional 5 percent of emissions could be mitigated by means of fuel switching to biofuels and/or further electrification of the CAD fleet. Residual emissions accounting for 23 percent of the operational control inventory could be offset with the purchases of high quality carbon credits in the voluntary carbon market. A comparison of the 2016 and 2006 operation control GHG emission inventories is shown in Figure 1-3.

**Figure 1-3. 2016 Operational Control GHG Emissions Comparison with the 2006 Baseline**

The breakdown of emissions by carbon management level and scope is presented in Table 1-6. Total GHG emissions in the Port Authority's inventory are 5,909,185 metric tons CO<sub>2</sub>e. Customer emissions account for half of total emissions (49.6 percent), followed by tenant emissions (46.1 percent). Operational control emissions are relatively small, amounting to just 4.0 percent. Employee emissions are the smallest, making up less than 1 percent of the entire Port Authority inventory. Note that the Port Authority inventory program requires that emissions from scope 1 and scope 2 sources be conducted annually and assessment of scope 3 emissions to be done periodically. For that reason, total scope 3 emissions of 5,674,529 metric tons CO<sub>2</sub>e for 2016 represent a composite value of the most recent assessment for a given source. An account of scope 3 emission estimates by year of assessment is provided as supplemental information in Appendix A: Scope 3 GHG Emissions by Year of Assessment.

<b>Table 1-6: Port Authority 2016 GHG Emissions Summary (metric tons CO<sub>2</sub>e)</b>					
<b>Carbon Management Level</b>	<b>Scope 1</b>	<b>Scope 2</b>	<b>Scope 3<sup>a</sup></b>	<b>Total</b>	<b>Total %</b>

Tenants			2,725,432	2,725,432	46.1%
Customers			2,928,601	2,928,601	49.6%
Employees			20,496	20,496	0.3%
<b>TOTAL</b>	<b>52,242</b>	<b>182,415</b>	<b>5,674,529</b>	<b>5,909,185</b>	<b>100%</b>

<sup>a</sup> The sum of scope 3 emissions reflects emission values for the most recent assessment of a given source.

Note: Totals may not match the column sums due to rounding.

In conformance with the GHG Protocol, the Port Authority reports biogenic emissions separately. Within the Port Authority inventory boundary, there are multiple sources of biogenic emissions, including CO<sub>2</sub> bi-product of municipal solid waste decomposition released from the closed Elizabeth Landfill and combustion of biofuels by the CAD main fleet, executive fleet, shadow fleet, and vehicles used by commuting employees. Most biogenic emissions come from energy recovery activities at the Essex County Resource Recovery facility, where municipal solid waste is combusted. A summary of biogenic emissions is presented in Table 1-7.

<b>Table 1-7: Port Authority 2016 Biogenic GHG Emissions Summary</b>			
<b>Carbon Management Level</b>	<b>Facility</b>	<b>Activity</b>	<b>Biogenic CO<sub>2</sub></b>
Operational Control	Elizabeth Landfill	Landfill Gas	557
	Fleet Vehicles	CAD Main Fleet	1,561
		Executive Fleet	14
Tenants	Multi-Facility	Shadow Fleet	1,190
Customers	Essex County Resource Recovery	Electricity Sold to Market	499,459
Employees	Multi-Facility	Employee Commuting	907
<b>TOTAL</b>			<b>503,689</b>

Note: Totals may not match the column sums due to rounding.

Table 1-8 presents anthropogenic emissions by line department and emissions categories across the carbon management spectrum. Sources grouped as “Multi-Department” include mobile combustion emissions from employees commuting to various Port Authority facilities and stationary combustion emissions from the maintenance and use of emergency generators and fire pumps located across the entire organization. Emissions from sources not expressly affiliated with one department such as electricity purchases and heating in support of central administrative functions are denoted as “Central Administration”.

Table 1-9 summarizes the Port Authority’s anthropogenic GHG emissions by emission category and emitting activity across the carbon management spectrum. For the Drayage Truck activity under “Attracted Travel”, this report accounts for emissions to the first point of rest to a maximum distance of 400 miles, which is about the distance travelled on a full tank of diesel by a drayage truck in a day. The first point of rest boundary reflects an industry good-practice for the management of GHG emissions (WPCI 2010). Drayage Truck emissions in this report compliments the results of the Port Commerce Department’s 2016 Multi-Facility Emission Inventory (Starcrest 2018) by estimating incremental emissions from the 16-county NYNJLINA boundary to the first point of rest.

## 2.0 STATIONARY COMBUSTION (SCOPE 1)

This chapter covers direct emissions from the combustion of fossil fuels in stationary equipment under the operational control of the Port Authority. Stationary combustion emissions are further broken down by three activities: building heating, emergency generators and fire pumps, and welding emissions associated with routine building maintenance.

### 2.1 BUILDINGS

The 2016 inventory assesses fuel combusted in buildings to produce heat or hot water using equipment in a fixed location. Natural gas is the predominant fuel for building heating, followed by heating oil at select facilities, and propane. The latter is associated with fire training exercises at JFK.

#### 2.1.1 Activity Data

The Port Authority's Office of Environmental and Energy Programs centrally collects information relating to natural gas purchases. This information was corroborated against natural gas invoices from suppliers, namely Central Hudson, Direct Energy, Great Eastern Energy, National Grid, and Public Service Electric & Gas (PSEG).

Table 2-1: Fuel Consumption in Buildings				
Department	Facility	Commodity	Consumption	Units
Aviation	JFK Airport	Heating Oil	52,552	gal
		Natural Gas	1,774,703	therm
		Propane	142,671	gal
	LGA Airport	Heating Oil	34,316	gal
		Natural Gas	502,475	therm
	EWR Airport	Heating Oil	119,345	gal
		Natural Gas	1,872,619	therm
	SWF Airport	Natural Gas	84,055	therm
	TEB Airport	Natural Gas	68,967	therm
Central Administration	PANYNJ Leased Office Space NJ	Natural Gas	144,408	therm
PATH	PATH Buildings	Heating Oil	33,584	gal
		Natural Gas	416,025	therm
Port	NJ Marine Terminals	Natural Gas	41,566	therm
	NY Marine Terminals	Natural Gas	35,837	therm
Real Estate	Real Estate NJ	Natural Gas	60,847	therm
	Real Estate NY	Natural Gas	19,678	therm
Tunnels, Bridges & Bus Terminals	Bus Terminals	Natural Gas	123,641	therm
	Tunnels and Bridges	Natural Gas	297,434	therm

Additionally, natural gas consumption was prorated for the months of January and December to capture consumption within the calendar year of the assessment. Limited data filling was conducted when missing information was identified; all data substitution qualified as *de minimis*. Heating oil consumption is monitored at the

facility level, and this information is collected from the facilities for the purposes of the inventory. Table 2-1 summarizes stationary fuel consumption in buildings by commodity.

### 2.1.2 Method

Emission estimates were developed in accordance with general reporting protocol (GRP) Chapter 12, “Direct Emissions from Stationary Combustion” (TCR 2013a). The GHG emission factors used to calculate the GHG emissions are shown in Table 2-2. The values in Table 2-2 are representative of U.S. pipeline-grade natural gas, No. 2 fuel oil (i.e., heating oil) and propane. The emission factors for CO<sub>2</sub> were then taken from GRP Table 12.1, and the emission factors for CH<sub>4</sub> and N<sub>2</sub>O were taken from GRP Table 12.9 (TCR 2017). When applicable, unit conversion was applied to match the unit of measurement of the activity data. In order to maintain consistency with the CAP emission factors in Table 2-3, an average high heating value of 1,026 British thermal units (Btu) per standard cubic foot was taken from the U.S. Environmental Protection Agency’s (EPA’s) “AP-42 Compilation of Air Pollutant Emission Factors” (EPA 1995; hereafter referred to as “EPA AP-42”), Section 1.4.

<b>Table 2-2: Stationary Combustion GHG Emission Factors</b>				
<b>Commodity</b>	<b>Units</b>	<b>CO<sub>2</sub></b>	<b>CH<sub>4</sub></b>	<b>N<sub>2</sub>O</b>
Natural gas	kg/therm	5.31	4.70 x 10 <sup>-4</sup>	1.00 x 10 <sup>-5</sup>
Heating oil (No. 2 fuel oil)	kg/gal	10.35	1.40 x 10 <sup>-3</sup>	8.40 x 10 <sup>-5</sup>
Propane	kg/gal	5.66	9.00 x 10 <sup>-4</sup>	5.40 x 10 <sup>-5</sup>

The CAP emission factors are based on values recommended by EPA AP-42, Chapters 1.3, “Fuel Oil Combustion” and 1.4, “Natural Gas Combustion” (EPA 1995). The sulfur dioxide (SO<sub>2</sub>) emission factor is based on assuming a 100 percent fuel sulfur conversion. The NO<sub>x</sub> and particulate matter (PM) emission factors are based on the premise that the natural gas was combusted in small [<100 million Btus (MMBtu) per hour (hr)] uncontrolled boilers. These values are presented in Table 2-3.

<b>Table 2-3: Stationary Combustion CAP Emission Factors</b>					
<b>Commodity</b>	<b>Units</b>	<b>SO<sub>2</sub></b>	<b>NO<sub>x</sub></b>	<b>PM<sub>2.5</sub></b>	<b>PM<sub>10</sub></b>
Natural gas	kg/therm	2.65 x 10 <sup>-5</sup>	4.42 x 10 <sup>-3</sup>	3.36 x 10 <sup>-4</sup>	3.36 x 10 <sup>-4</sup>
Heating oil (No. 2 fuel oil)	kg/gal	9.66 x 10 <sup>-5</sup>	9.07 x 10 <sup>-3</sup>	6.99 x 10 <sup>-4</sup>	1.04 x 10 <sup>-3</sup>
Propane	kg/gal	2.21 x 10 <sup>-5</sup>	5.90 x 10 <sup>-3</sup>	3.18 x 10 <sup>-4</sup>	3.18 x 10 <sup>-4</sup>

### 2.1.3 Results

Table 2-4 summarizes stationary combustion GHG emissions by facility and department. Table 2-5 presents stationary combustion CAP emissions.

## 2.2 EMERGENCY GENERATORS AND FIRE PUMPS

All facilities under Port Authority's operational control have stationary engine generators for use in emergency situations. These emergency generators and fire pumps are typically diesel fired, but the Port Authority does have some gasoline- and natural gas-fired generators. The emergency generators and fire pumps are tested periodically throughout the year.

### 2.2.1 Activity Data

The Port Authority provided annual runtime and fuel usage data for emergency generators and fire pumps at JFK, LGA, EWR, New York Marine Terminals, and New Jersey Marine Terminals. Actual annual runtime or fuel usage data for emergency generators and fire pumps were not available for other Port Authority facilities. Electricity usage

data is a reasonable surrogate for emergency generator and fire pump usage data (a facility with higher electricity needs will maintain more back-up generators than a facility with lower electricity needs) and electricity usage data were available for all Port Authority facilities. For these facilities, estimated emissions were calculated using the surrogate emission factors described above and applying them against the electricity usages for each facility. These methodologies are based on engineering estimates and are qualified as *de minimis*.

## 2.2.2 Method

GHG and CAP emissions for the five facilities with actual activity data (i.e., JFK, LGA, EWR, New York Marine Terminals and New Jersey Marine Terminals) were estimated using standard emission factors (TCR 2017) and EPA AP-42, Section 3.3, “Gasoline and Diesel Industrial Engines” (EPA 1995). The emission factors are shown in Table 2-6.

<b>Table 2-6: Emergency Generator and Fire Pump Emission Factors</b>				
<b>Pollutant</b>	<b>Unit</b>	<b>Diesel Fuel</b>	<b>Gasoline</b>	<b>Natural Gas</b>
CO <sub>2</sub>	kg/MMBtu	72.93	60.77	53.10
CH <sub>4</sub>	kg/MMBtu	4.29 x 10 <sup>-03</sup>	3.85 x 10 <sup>-03</sup>	4.70 x 10 <sup>-03</sup>
N <sub>2</sub> O	kg/MMBtu	2.57 x 10 <sup>-03</sup>	2.31 x 10 <sup>-03</sup>	1.00 x 10 <sup>-04</sup>
NO <sub>x</sub>	kg/MMBtu	2.00 x 10 <sup>-00</sup>	7.39 x 10 <sup>-01</sup>	1.85 x 10 <sup>-00</sup>
SO <sub>x</sub>	kg/MMBtu	1.32 x 10 <sup>-01</sup>	3.81 x 10 <sup>-02</sup>	2.67 x 10 <sup>-04</sup>
PM	kg/MMBtu	1.41 x 10 <sup>-01</sup>	4.54 x 10 <sup>-02</sup>	4.57 x 10 <sup>-03</sup>

GHG and CAP emissions for the remaining Port Authority facilities were estimated using an engineering estimate. Alternate GHG and CAP emission factors were developed as the ratio of emergency generators and fire pump emissions and electricity consumption at JFK, LGA, EWR, New York Marine Terminals, and New Jersey Marine Terminals. Table 2-7 provides the relative emission factors for emergency generators and fire pumps applied to this assessment.

<b>Table 2-7: Emergency Generator and Fire Pump Alternate Emission Factors</b>			
<b>Pollutant</b>	<b>Unit</b>	<b>Emergency Generator</b>	<b>Fire Pump</b>
CO <sub>2</sub>	kg/MWh	1.63	0.32
CH <sub>4</sub>	kg/MWh	9.62 x 10 <sup>-05</sup>	1.86 x 10 <sup>-05</sup>
N <sub>2</sub> O	kg/MWh	5.73 x 10 <sup>-05</sup>	1.12 x 10 <sup>-05</sup>
NO <sub>x</sub>	kg/MWh	4.48 x 10 <sup>-02</sup>	8.70 x 10 <sup>-03</sup>
SO <sub>x</sub>	kg/MWh	2.93 x 10 <sup>-03</sup>	5.72 x 10 <sup>-04</sup>
PM <sub>2.5</sub>	kg/MWh	3.13 x 10 <sup>-03</sup>	6.12 x 10 <sup>-04</sup>
PM <sub>10</sub>	kg/MWh	3.13 x 10 <sup>-03</sup>	6.12 x 10 <sup>-04</sup>

## 2.2.3 Results

Total emergency generator and fire pump GHG and CAP emission estimates are shown in Table 2-8.

<b>Table 2-8: GHG &amp; CAP Emissions from Emergency Generators and Fire Pumps (metric tons)</b>			
<b>Pollutant</b>	<b>Emergency Generators</b>	<b>Fire Pumps</b>	<b>Total</b>
CO <sub>2</sub>	746.74	140.46	887.20
CH <sub>4</sub>	0.04	0.01	0.05
N <sub>2</sub> O	0.03	0.01	0.03
CO <sub>2</sub> e	755.79	142.17	897.95
NO <sub>x</sub>	20.49	2.38	22.87
SO <sub>x</sub>	1.34	0.16	1.50
PM <sub>2.5</sub>	1.43	0.17	1.60
PM <sub>10</sub>	1.43	0.17	1.60

Note: Totals may not match the column sums due to rounding.

## 2.3 WELDING GASES

Limited welding activity takes place within the boundary for the Port Authority inventory, and its impact on Port Authority emissions is negligible. An engineering estimate was developed to quantify the level of welding gas emissions, correlating the emitting activity to the dollar amount of welding gas purchased. When surveyed for the 2010 inventory, LGA reported spending \$866 on welding gas (Port Authority 2012a). Typically, acetylene costs \$1.24 per standard cubic foot (WeldingWeb 2012). Assuming that all purchased welding gas was acetylene and that all purchased gas was used, it was determined by stoichiometry that 77.8 kg of CO<sub>2</sub> were emitted at LGA. Furthermore, assuming that the same level of welding activity occurred at all five airports and at the two marine terminals, total welding gas emissions at the Port Authority were estimated to be 0.5 metric tons of CO<sub>2</sub> in 2010. The same engineering emission estimate (or *de minimis*) was carried over to calendar year 2016.

### 3.0 MOBILE COMBUSTION (SCOPE 1)

Mobile combustion emissions result from the combustion of fuels by on-road vehicles, non-road vehicles, and portable equipment that is owned and operated by the Port Authority. The Port Authority's Central Automotive Division (CAD) oversees the procurement and maintenance of on-road vehicles, most non-road vehicles, and some portable equipment. Additionally, PATH operates and services a small number of non-road vehicles and portable equipment.

#### 3.1 CENTRAL AUTOMOTIVE DIVISION FLEET

CAD is in charge of purchasing and maintaining the Port Authority's fleet of vehicles. CAD relies on records either from the fuel management system or from fuel vendor invoices—as in the case of compressed natural gas (CNG)—to track fleet fuel consumption. Additionally, CAD encourages on-road vehicle operators to log mileage information when filling up to better estimate methane, nitrous oxide and CAP emissions. The CAD fleet consumes conventional fuels like gasoline and diesel as well as alternative fuels such as compressed natural gas (CNG), gasoline with an 85 percent ethanol blend (E85), liquified petroleum gas (LPG), and diesel with a 20 percent biodiesel blend (B20).

Table 3-1: CAD Fuel Consumption summarizes CAD fleet fuel consumption by fuel type in 2015 (Port Authority 2017a).

<b>Table 3-1: CAD Fuel Consumption</b>			
<b>Activity</b>	<b>Commodity</b>	<b>Units</b>	<b>Consumption</b>
CAD Main Fleet	Biodiesel (B20)	gal	261,986
CAD Main Fleet	CNG	scf	7,108,412
CAD Main Fleet	Diesel	gal	32,274
CAD Main Fleet	LPG	gal	1,550
CAD Main Fleet	Gasoline (E10)	gal	1,155,923
CAD Main Fleet	E85	gal	82,112
Executive Fleet	Diesel	gal	28
Executive Fleet	Gasoline (E10)	gal	25,087

##### 3.1.1 Activity Data

For the purpose of the fuel tracking, the CAD fleet is divided between the CAD Main Fleet and the Executive Fleet, which is a subset of vehicles assigned to specific functions within the Port Authority. The data flow for tracking transportation fuel consumption is shown in Figure 3-1. The main fleet is composed of 2,664 vehicles, which includes on-road and non-road vehicles as well as portable equipment. CAD retains the services of Sprague, a fuel management contractor, to track the volume of fuel dispensed from a network of authorized fuel stations by means of dedicated fuel cards. For each fuel type, the volume of fuel dispensed was used to calculate CO<sub>2</sub> emissions from the main fleet. The CAD also rents vehicles for various projects on an as-needed basis. There are approximately 250 such vehicles being rented at any given time (Port Authority 2016e). The fuel consumption from

these rental vehicles is also tracked by Sprague and included in all CAD fuel consumption totals.

The Port Authority Office of the Treasury tracks fuel consumption for a subset of vehicles by means of branded fuel cards (e.g., Shell Fuel Card). This includes 25 vehicles used by executives, 35 security vehicles associated with the Port Authority's Inspector General's office, and two vehicles used in association with training activities in Morris County, New Jersey; collectively, all 62 vehicles are referred to in the inventory as the Executive Fleet. The Office of the Treasury maintains a financial record of fuel purchases. To convert expenditures to fuel volume, the 2016 annual average fuel price of \$2.25 per gallon for the middle Atlantic region was applied (EIA 2017). This analysis also assumed that 99.9 percent of fuel consumption was gasoline and the remaining 0.1 percent was diesel based on the actual record for 2012, when information on fuel volume by fuel type was available.

**Figure 3-1. Fuel Tracking for the Port Authority Vehicle Fleet**

Activity data for estimating CAP emissions came from CAD in the form of vehicle activity. Vehicle activity came in different units of measurement according to the specific segments of the fleet. For most highway vehicles, activity data consisted of recorded miles traveled. For smaller segments of the fleet, such as the executive fleet and non-highway vehicles (e.g., forklifts), fuel consumption served as the activity data. The selection of the best emission factor based on available activity data is discussed in Section 3.1.2 below for each fleet segment.

### **3.1.2 Method**

GHG emission estimates were calculated as the product of fuel use and fuel-specific emission factors. Carbon dioxide emissions were estimated by multiplying the fuel use by the appropriate emission factor from GRP Table 13.1 (TCR 2017). The majority of fuel consumed by Port Authority contains some biofuel (either E10 or B20). For these biofuel blends, attention was given to distinguishing between anthropogenic and biogenic emissions. This was accomplished by correlating the fossil fuel-specific emission factor to the volume of fossil fuel consumed. For example, for a volume of 100 gallons of E10, anthropogenic CO<sub>2</sub> emissions equal:

$$100 \text{ gal of E10} \times 90 \text{ percent fossil fuel by volume} \times 8.78 \text{ kg CO}_2/\text{gal} = 790.2 \text{ kg CO}_2$$

Biogenic CO<sub>2</sub> emission estimates (i.e., those generated during the combustion or decomposition of biologically based material such as biodiesel or ethanol) are calculated by correlating the biofuel-specific emission factor to the volume of biofuel consumed. For example, for a volume of 100 gallons of E10, biogenic CO<sub>2</sub> emissions equal:

$$100 \text{ gal of E10} \times 10 \text{ percent ethanol by volume} \times 5.75 \text{ kg CO}_2/\text{gal} = 57.5 \text{ kg CO}_2$$

For all fuel types, CH<sub>4</sub> and N<sub>2</sub>O emissions were assessed using an engineering estimate, based on the ratio of CO<sub>2</sub> to CH<sub>4</sub> and N<sub>2</sub>O emissions taken from GRP Table 13.9 (TCR 2017). The emission factors used to calculate the emissions are presented in Table 3-2.

<b>Table 3-2: Emission Factors for Onroad Transportation Fuels</b>					
<b>Fuel Type</b>	<b>Percentage Biofuels</b>	<b>Fossil Fuel CO<sub>2</sub> (kg/gal or kg/ccf)</b>	<b>Biogenic CO<sub>2</sub> (kg/gal)</b>	<b>CH<sub>4</sub> (kg/kg of CO<sub>2</sub>)</b>	<b>N<sub>2</sub>O (kg/kg of CO<sub>2</sub>)</b>
Gasoline (E10)	10%	8.78	5.75	0.000059	0.000036
Diesel #2	0%	10.21	9.45	0.000059	0.000036
Biodiesel (B20)	20%	10.21	9.45	0.000059	0.000036
E85	85%	8.78	5.75	0.000059	0.000036
CNG	0%	5.4	0	0.000059	0.000036
Propane	0%	5.72	0	0.000059	0.000036

Because a number of commercial transportation fuels combine petroleum and biofuel products, it is necessary to adjust the standard emission factors to differentiate between anthropogenic and biogenic mobile combustion emissions. The latter corresponds to the combustion of the biofuel volume in a given commercial fuel blend. For instance, commercial gasoline (E10) is a mixture of a petroleum product (90 percent) and bioethanol (10 percent); therefore, the effective biogenic emission factor for commercial gasoline was calculated as the product of the ethanol carbon content and the concentration of ethanol in the commercial fuel blend. Table 3-3 shows the effective CO<sub>2</sub> emission factors for petroleum and biofuel blends consumed by the CAD fleet.

<b>Table 3-3: Effective CO<sub>2</sub> Emission Factors of Biofuel Blends</b>			
<b>Fuel Type</b>	<b>Percentage Biofuels</b>	<b>Anthropogenic CO<sub>2</sub> (kg/gal)</b>	<b>Biogenic CO<sub>2</sub> (kg/gal)</b>
Gasoline (E10)	10%	7.90	0.58
Biodiesel (B20)	20%	8.17	1.89
E85	85%	1.32	4.89

CAP emission factors for highway vehicles are from the EPA MOtor Vehicle Emissions Simulator (MOVES 2014a) (EPA 2014a). These emission factors are expressed in units of grams per mile based on model year and vehicle type for the 2016 inventory. CAP emissions from diesel vehicles were assumed to come from B20 fuel, because that is the primary diesel fuel used at Port Authority. Similarly, CAP emissions from vehicles using E10 fuel used MOVES emission factors that were modeled with the properties of E10 fuel. Flex Fueled vehicles were assumed to be burning E85. These emission factors were then multiplied by the 2016 estimates of mileage per vehicle provided by

the CAD to obtain CAP emissions. There was no mileage data available for the rental vehicles that CAD uses. Since these vehicles are primarily light duty pickups, the average VMT from CAD pickup trucks (6,752 miles in 2016) was used as a stand-in. This VMT is then multiplied by the number of rental vehicles (approximately 250) and the MOVES 2014a emissions factor for a 2016 light duty pickup truck to estimate CAP emissions from rental vehicles.

Non-highway CAP emissions were calculated by multiplying total fuel consumption by the national average emission factors from EPA's MARKet ALlocation (MARKAL) model database (Pechan 2010). CAP emissions for bulk CNG and propane were estimated by multiplying total fuel consumption by the appropriate MARKAL emission factors. The CAP estimates for the executive fleet and the security and training vehicles were based on the per-gallon emission factors from EPA's MARKAL database (Pechan 2010), because no information on mileage per vehicle was available.

### 3.1.3 Results

Table 3-4 presents GHG and CAP emission estimates for the CAD Main Fleet by fuel type. Table 3-5 shows the GHG and CAP emissions by fuel type from the Executive Fleet. The reliance on biofuel blends, the portion of biogenic CO<sub>2</sub> emissions for CAD is sizable amounting to 1,575 tCO<sub>2</sub>e in 2016.

<b>Table 3-4: GHG &amp; CAP Emissions from the CAD Main Fleet (metric tons)</b>

## 3.2 PATH DIESEL EQUIPMENT

PATH owns and operates certain track maintenance vehicles that are not accounted for by the CAD. PATH equipment includes a small number of non-road vehicles and portable equipment.

### 3.2.1 Activity Data

PATH non-road and portable equipment burns diesel fuel exclusively. Annual fuel consumption is tracked for each individual piece of equipment. This information serves as the activity data for GHG and CAP emission assessments. For the 2016 inventory, diesel fuel consumption was provided by Port Authority (Port Authority 2017l).

### 3.2.2 Method

Carbon dioxide emission estimates are calculated based on the gallons of diesel fuel multiplied by the appropriate emission factor from GRP Table 13.1 (TCR 2017). Methane and nitrous oxide emission estimates are calculated based on the per-gallon diesel emission factor for non-highway equipment, from GRP Tables 13.7 and 13.8, respectively (TCR 2017).

The emission factors for CAP for diesel equipment used in the PATH system were calculated based on emission factors from the EPA MARKAL database (Pechan 2010).

### 3.2.3 Results

Total GHG and CAP emissions for PATH diesel equipment are shown in Table 3-6.

<b>Table 3-6: GHG &amp; CAP Emissions from PATH Diesel Equipment (metric tons)</b>							
<b>CO<sub>2</sub></b>	<b>CH<sub>4</sub></b>	<b>N<sub>2</sub>O</b>	<b>CO<sub>2</sub>e</b>	<b>SO<sub>x</sub></b>	<b>NO<sub>x</sub></b>	<b>PM<sub>2.5</sub></b>	<b>PM<sub>10</sub></b>

## 4.0 FUGITIVE EMISSIONS (SCOPE 1)

Fugitive emissions are intentional and unintentional releases of GHGs that are not the result of fossil fuel combustion. This chapter covers fugitive emissions from equipment or activities under the operational control of the Port Authority. More specifically, refrigeration and fire protection equipment charged with substitutes for ozone-depleting substances (ODSs), as well as biogas gas emanating from a historical landfill.

### 4.1 USE OF REFRIGERANTS

Emissions of HFCs and PFCs from stationary and mobile air conditioning (AC) equipment are the result of fugitive release over the operational life of the equipment. Note that not all refrigerants are reportable according to best carbon accounting practices. Ozone depleting substances such as refrigerants R-22, R-12, and R-11 are not required to be reported for carbon management purposes because their production is already being phased out under the Montreal Protocol.

#### 4.1.1 Method

Emission estimates were developed in accordance with GRP Chapter 16, “Direct Fugitive Emissions from the Use of Refrigeration and Air Conditioning Equipment” (TCR 2013a). The 2016 approach for estimating refrigerant fugitive emissions is consistent with previous years’ assessments and follows the decision tree shown in Figure 4-1. The 2016 inventory leverages AC equipment surveys previously conducted for the EY2012 and EY2014. All refrigerant fugitive emission estimates were developed using method Option 2 with some adjustments that are described below, except for LGA, where a modified simple mass balance equation was applied (i.e., method Option 1). Note that all direct fugitive emissions from the use of refrigerants qualify as *de minimis*.

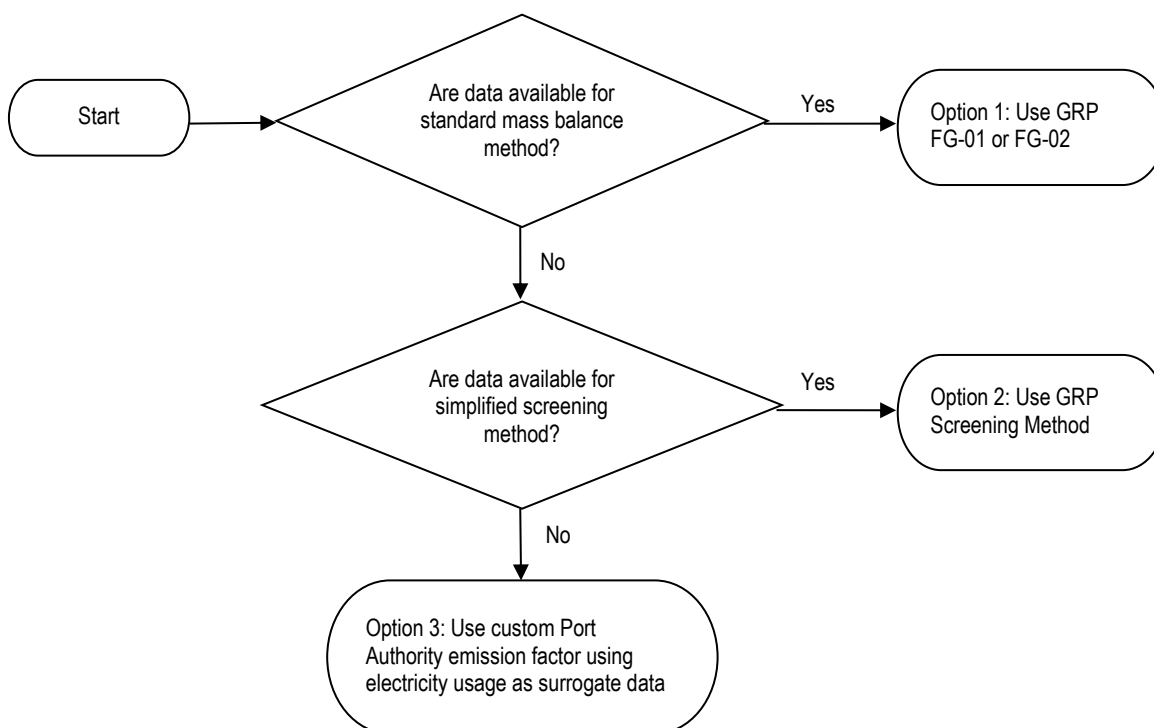

Option 1: The methodology relies on a mass-balance approach to account for changes in refrigerant inventory levels (additions as well as subtractions) and net increases in nameplate capacity.

Option 2: Refrigerant fugitive emission estimates using Option 2 rely on an AC equipment count and information about the type of refrigerant, typical annual utilization, the equipment’s nameplate refrigerant charge, and equipment’s application (e.g., chiller or residential/commercial AC, including heat pump). Rates of refrigerant release are then correlated to each AC equipment profile. The resulting emission estimates for each HFC and PFC are then converted to units of CO<sub>2</sub>e using the appropriate GWP factors to determine total HFC and PFC emissions.

A substantial effort was made to ensure that refrigerant emissions for the 2016 inventory were estimated following a consistent procedure across all Port Authority facilities following the GRP equation 16e (TCR 2013a). For most Port

Authority facilities, the refrigerant charge or capacity was known based on information obtained from facility surveys. However, in certain cases, survey information provided only cooling equipment capacity. In those cases, existing available data were used to develop a correlation between the equipment capacity in tons of refrigeration and refrigerant charge in kg for various size units in Btu/hr. The following linear equation was developed and used to estimate the refrigerant capacity for those facilities where only the cooling capacity was available:  $y \text{ (kg of charge)} = 0.574x \text{ (tons capacity)} + 7.187$ .

**Figure 4-1. Method Selection to Quantify Fugitive Emissions from AC Equipment**

#### 4.1.2 Results

GHG emission estimates for refrigerants used by the Port Authority during 2016 are shown in Table 4-1. This table excludes non-reportable HCFCs and chlorofluorocarbons (CFCs), such as R-22. Shaded cells refer to facilities for which air conditioning systems have been previously surveyed and found not to contain any GHGs. Note that starting with EY2016, emissions are no longer being assessed for AirTrain JFK or AirTrain Newark because the AirTrain system was recategorized as a scope 3 source.

<b>Table 4-1: Refrigerant Emissions by Facility and ODS Substitute (metric tons CO<sub>2</sub>e)</b>

## 4.2 USE OF FIRE SUPPRESSANTS

Fire protection systems charged with reportable ODS substitutes often service areas with specialized equipment such as high-value electronics, including server and communication rooms.

For previous inventory years, a survey was distributed to facility managers requesting a list of fire protection equipment (e.g., centralized system, hand-held devices), the nature of the fire suppressant used to charge such equipment, and the amount of fire suppressant purchased for equipment recharge (as a proxy for GHG releases). Based on the survey responses, CO<sub>2</sub> and FM-200® are the common GHGs to be reported in the event of equipment discharge. Previous surveys indicated that the following facilities use reportable GHGs as fire suppressants:

- LaGuardia (LGA) Airport: FM-200;
- Stewart (SWF) Airport: CO<sub>2</sub>;
- Newark (EWB) Airport: CO<sub>2</sub>;
- George Washington Bridge: FM-200;
- Holland Tunnel: FM-200;
- Lincoln Tunnel: FM-200;

- Staten Island Bridges: FM-200; and
- PATH Buildings: CO<sub>2</sub> and FM-200.

The first step in quantifying emissions from fire suppressants for the 2016 inventory year was to survey these facilities known to have fire protection equipment that uses reportable GHGs. In addition to the facilities listed above, a survey was also distributed to obtain information on firefighting equipment for George Washington Bridge Bus Station, which was previously unknown. Based on the survey response, there is fire protection equipment that uses FM-200 for fire suppression at George Washington Bridge Bus Station as well.

The Port Authority indicated that in 2016 there were fire suppressant releases totaling 111 kilograms of CO<sub>2</sub>. The CO<sub>2</sub> emissions released in 2016 are attributed to portable fire extinguishers associated with the PATH Buildings. No other releases occurred from the facilities surveyed for the 2016 inventory year. Table 4-2 summarizes the results of the 2016 fire suppressant survey.

<b>Table 4-2: Fugitive Emissions from Fire Protection Equipment (metric tons CO<sub>2</sub>e)</b>

Lincoln Tunnel	N/A	No release
Staten Island Bridges	N/A	No release
PATH Buildings	0.111	No release

### 4.3 HISTORIC ELIZABETH LANDFILL

The Port Authority property known as “Port Elizabeth” in Elizabeth, New Jersey, is part of the Port Commerce department. The Port Elizabeth property sits atop a former landfill site where household and industrial waste was dumped until the landfill closed in 1970. It is believed that dumping began at the Elizabeth Landfill (a.k.a. the Kapkowski Road Landfill) site sometime in the 1940s (Wiley 2002). Although the historic landfill boundary cannot be determined with certainty, the current landfill boundary based on land ownership is known and defined as the area south of Bay Avenue between the Conrail railroad tracks to the west and McLester Street to the east for a total surface area of 178 acres.

Although the Port Elizabeth property is leased to tenants, the Port Authority maintains shared operational control of property improvement activities. These activities are governed by the Tenant Construction and Alteration Process, which requires close coordination between the Port Authority and its business partners (i.e., tenants) when making “alterations and minor works at existing [Port Authority] facilities in addition to all new construction” (TCAP 2010, p. 1). Therefore, fugitive landfill gas emissions are reported as scope 1 emissions.

### 4.3.1 Activity Data

Air emissions from landfills come from gas generated by the decomposition of waste in the landfill. The composition of landfill gas is roughly 50 percent CH<sub>4</sub> and 50 percent CO<sub>2</sub> by volume, with additional relatively low concentrations of other air pollutants, including volatile organic compounds (VOCs). Activity data in the form of total solid waste deposited (short tons) in the historic Elizabeth Landfill were used to estimate the CH<sub>4</sub> emissions from the landfill using the first-order decay model.

Because of a lack of waste emplacement records, the annual mass of waste received at the site was calculated as the product of the average refuse depth of 8.33 feet as measured by a geological survey (Port Authority 1974), refuse density of 0.58 tons (EPA 1997), and the area of the historical landfill under current Port Authority operational control of 178 acres.<sup>2</sup> Thus, waste emplaced was estimated to be on the order of 1.39 million short tons. Assuming that the landfill operated from 1940 through 1970, the annual rate of waste emplacement was determined to be 44,735 tons per year.

### 4.3.2 Method

Emissions estimates were developed in accordance with “Local Government Operations Protocol,” Chapter 9, “Solid Waste Management” (LGO 2010). Default values were applied for the percentage of waste that is anaerobically degradable organic carbon. The model runs with the assumptions that the CH<sub>4</sub> fraction of the landfill gas is 50 percent and that 10 percent of the CH<sub>4</sub> is oxidized prior to being emitted into the atmosphere. The decay constant (i.e., k-value) was set at 0.057, corresponding to areas that regularly receive more than 40 inches of annual rainfall. The model calculates biogenic CO<sub>2</sub> emissions, which are reported separately from anthropogenic emissions. A similar model, EPA’s Landfill Gas Emissions Model (LandGEM) (EPA 2005), was used to estimate VOC emissions.

### 4.3.3 Results

The 2016 GHG and CAP emission estimates for the historic Elizabeth Landfill are shown in Table 4-3. Additionally, the historic Elizabeth Landfill emitted 557 tons of biogenic CO<sub>2</sub>.

<b>Table 4-3: GHG &amp; CAP Emissions from the Historic Elizabeth Landfill (metric tons)</b>		
<b>CH<sub>4</sub></b>	<b>CO<sub>2</sub>e</b>	<b>VOC</b>
166	3,491	0.7

<sup>2</sup> This value was measured in an ArcGIS environment from maps provided by Port Authority staff, titled “PNPEFacMap2007draft5-07.pdf” and “Refuse\_fill\_rev.pdf.”

## 5.0 PURCHASED ELECTRICITY (SCOPE 2)

### 5.1 BUILDINGS

This section discusses electricity purchases for buildings and commercial space under the operational control of the Port Authority. For a total of five facilities (JFK, LGA, SWF, PABT and Teleport), electricity is purchased by the Port Authority and sub-billed to its tenants; therefore, the portion of electricity consumption attributed to the Port Authority is the difference between total electricity purchased and the amount sub-billed to tenants. Note that emissions resulting from electricity consumption by tenants is reported as a scope 3 source.

#### 5.1.1 Activity Data

The Port Authority's Office of Environmental and Energy Programs centrally collects information relating to electricity purchases from utility invoices. This information was corroborated against monthly statements supplied by the electric utilities, namely, Central Hudson, Constellation Energy, New York Power Authority (NYPA), Public Service Electric & Gas (PSEG), and South Jersey Energy. Additionally, electricity consumption was prorated for the months of January and December to capture consumption within the calendar year of the assessment. Limited data filling was conducted when missing information was identified; all data substitution qualified as *de minimis*. Table 5-1: Building Electricity Consumption by Facility presents electricity consumption, where consumption is summed by taking into consideration the carbon content of the electricity supply as explained in Section Method.

#### 5.1.2 Method

Emission estimates were developed in accordance with GRP Chapter 14, "Indirect Emissions from Electricity Use" (TCR 2013a). According to this methodology, the emissions factor corresponds to the carbon content of electricity delivered if that information is known by the supplier. This is the case of electricity delivered by the Kennedy International Airport Cogeneration (KIAC) to JFK. In all other cases, a reference carbon content from the Emissions & Generation Resource Integrated Database (eGRID) was assigned based on the geographical location of the end user (EPA 2017c). For facilities located in New York City, the emission factors for the Northeast Power Coordinating Council (NPCC) - New York City/Westchester (NYCW) eGRID subregion were used. For facilities located in upstate New York, the NPCC - Upstate New York (NYUP) eGRID subregion factors were applied. For facilities located in New Jersey, the emission factors for the Reliable First Corporation East (RFCE) eGRID subregion were used. The emission factors used to estimate the GHG emissions associated with electricity consumption are shown in Table 5-2.

Table 5-1: Building Electricity Consumption by Facility			
Department	Facility	eGRID Region/ Generator	Consumption (kWh)
Aviation	JFK Airport	Electricity-KIAC	78,885,203

<b>TOTAL</b>			<b>357,063,006</b>

Note: Totals may not match the column sums due to rounding.

Table 5-2: Electricity Consumption GHG Emission Factors				
eGRID Subregion/Generator	Unit	CO <sub>2</sub>	CH <sub>4</sub>	N <sub>2</sub> O
NYCW	kg/kWh	3.02 x 10 <sup>-1</sup>	1.11 x 10 <sup>-5</sup>	1.35 x 10 <sup>-6</sup>
NYUP	kg/kWh	1.67 x 10 <sup>-1</sup>	1.39 x 10 <sup>-5</sup>	1.88 x 10 <sup>-6</sup>
RFCE	kg/kWh	3.76 x 10 <sup>-1</sup>	3.35 x 10 <sup>-5</sup>	5.09 x 10 <sup>-6</sup>
KIAC	kg/kWh	4.26 x 10 <sup>-1</sup>	3.05 x 10 <sup>-5</sup>	7.23 x 10 <sup>-6</sup>

Table 5-3 shows the CAP emission factors used for the 2016 electricity emission estimates. eGRID provided SO<sub>2</sub> and NO<sub>x</sub> emission factors for eGRID regions (EPA 2017c). Emission factors for PM were calculated in proportion to SO<sub>2</sub> emissions assessed by the 2014 EPA National Emissions Inventory (EPA 2017d). This is a reasonable approach because SO<sub>2</sub> is a significant contributor of total PM and thus a strong indicator of PM levels. To find the proportion to use, total emissions from all electric generating processes were summed for plants in each state for SO<sub>2</sub>, PM<sub>2.5</sub>, and PM<sub>10</sub> in the 2014 NEI. PM emission factors were calculated as the product of statewide PM emissions and the SO<sub>2</sub> emission factor divided by the sum of statewide SO<sub>2</sub> emissions, as shown in Equation 5-1:

$$Ef_{PM} = Ef_{SO_2} \times \frac{\sum_{State} PM}{\sum_{State} SO_2} \quad (5-1)$$

Where:

$Ef_{PM}$  = emission factor for either PM<sub>2.5</sub> or PM<sub>10</sub>

$Ef_{SO_2}$  = emission factor for SO<sub>2</sub> provided by eGRID

PM = value of particulate matter state emissions for either PM<sub>2.5</sub> or PM<sub>10</sub>

SO<sub>2</sub> = value of sulfur dioxide state emissions

<b>Table 5-3: Electricity Consumption CAP Emission Factors</b>					
<b>eGRID Subregion/Generator</b>	<b>Unit</b>	<b>SO<sub>2</sub></b>	<b>NO<sub>x</sub></b>	<b>PM<sub>2.5</sub></b>	<b>PM<sub>10</sub></b>

## 5.2 RAIL SYSTEMS

The Port Authority owns three rail systems: PATH, AirTrain JFK, and AirTrain Newark. Port Authority maintains operational control of PATH, while the AirTrain systems are operated by Bombardier Transportation. This section covers the development of emissions resulting from indirect purchased electricity from the PATH system, which is under the operational control of the Port Authority. Emissions for the AirTrain systems are categorized as scope 3 and are discussed in Section 11.2.

### 5.2.1 Activity Data

The Port Authority's Office of Environmental and Energy Programs centrally collects information relating to electricity purchases from Constellation Energy and South Jersey Energy associated with electricity purchases for PATH trains. This information was corroborated against monthly statements supplied by the electric utility. Additionally, electricity consumption was prorated for the months of January and December to capture consumption within the calendar year of the assessment. Total consumption in 2016 amounted to 100,293,858 kWh.

### 5.2.2 Method

As described in Section 5.1.3, emission estimates are developed in accordance with GRP Chapter 14, "Indirect Emissions from Electricity Use" (TCR 2013a). The GHG emission factors used to calculate the GHGs associated with electricity consumption are shown in Table 5-2. For the PATH Rail System, the emission factors for the RFCE subregion were applied. Table 5-3 shows the CAP emission factors used for the 2016 electricity emission estimates.

### 5.2.3 Results

GHG emission estimates were developed from records of electricity consumption (i.e., utility statements). Table 5-6 summarizes GHG and CAP emissions associated with operation of the PATH rail system.

<b>Table 5-6: GHG &amp; CAP Emissions from Electricity Consumption in Rail Systems (metric tons)</b>								
<b>Activity</b>	<b>CO<sub>2</sub></b>	<b>CH<sub>4</sub></b>	<b>N<sub>2</sub>O</b>	<b>CO<sub>2</sub>e</b>	<b>SO<sub>2</sub></b>	<b>NO<sub>x</sub></b>	<b>PM<sub>2.5</sub></b>	<b>PM<sub>10</sub></b>
PATH Rail System	37,734	3.36	0.51	37,962	87.57	37.76	34.37	35.86

## 6.0 PURCHASED STEAM, HEATING, AND COOLING (SCOPE 2)

This chapter discusses indirect emissions associated with energy purchases or acquisitions in the form of steam, heating, and cooling from the KIAC facility and Con Edison.

### 6.1 KIAC HEATING AND COOLING

The Port Authority purchases thermal energy in the form of heating and cooling from KIAC to service JFK. While the KIAC facility is owned by the Port Authority and sits within Port Authority property, emissions from the plant do not fall within the operational control boundary because the facility is operated by Calpine Corporation. On the other hand, the Port Authority reports emissions associated with thermal energy purchases. These are calculated as a function of energy purchases multiplied by a KIAC-specific emission metric.

#### 6.1.1 Activity Data

The Port Authority provided separate monthly thermal energy purchase data for JFK. Thermal energy in the form of cooling and heating was billed separately. Thermal consumption for heating and cooling amounted to 51,018 and 97,908 MMBtu respectively.

#### 6.1.2 Method

The heating and cooling GHG and PM emission factors for KIAC were determined as described in Section 7.1. The resulting heating and cooling emission factors are presented in Table 6-1: KIAC Thermal Emission Factors.

<b>Table 6-1: KIAC Thermal Emission Factors</b>							
<b>Metric</b>	<b>CO<sub>2</sub></b>	<b>CH<sub>4</sub></b>	<b>N<sub>2</sub>O</b>	<b>SO<sub>2</sub></b>	<b>NO<sub>x</sub></b>	<b>PM<sub>2.5</sub></b>	<b>PM<sub>10</sub></b>
Heating (kg/MMBtu)	62.35	4.47 x 10 <sup>-3</sup>	1.06 x 10 <sup>-3</sup>	3.12 x 10 <sup>-4</sup>	1.33 x 10 <sup>-2</sup>	3.52 x 10 <sup>-3</sup>	3.52 x 10 <sup>-3</sup>
Cooling (kg/MMBtu)	62.35	4.47 x 10 <sup>-3</sup>	1.06 x 10 <sup>-3</sup>	3.12 x 10 <sup>-4</sup>	1.33 x 10 <sup>-2</sup>	3.52 x 10 <sup>-3</sup>	3.52 x 10 <sup>-3</sup>

#### 6.1.3 Results

Table 6-2 provides GHG and CAP emission estimates for the heating and cooling purchased from KIAC by the Port Authority to service JFK.

<b>Table 6-2: GHG &amp; CAP Emissions from KIAC Thermal Energy Purchases (metric tons)</b>

<b>TOTAL</b>	<b>9,286</b>	<b>0.67</b>	<b>0.16</b>	<b>9,349</b>	<b>0.05</b>	<b>1.98</b>	<b>0.52</b>	<b>0.52</b>

Note: Totals may not match the column sums due to rounding.

## 6.2 CON EDISON STEAM

The PABT and WTC purchase steam from Con Edison for building heating purposes. The attributes of the Con Edison 59<sup>th</sup> Street Generating Station were used to assess the carbon intensity of steam deliveries.

### 6.2.1 Activity Data

The Port Authority monitors monthly steam consumption data at PABT and WTC. Annual consumption in 2016 was 55,408 and 40,862 thousand pounds of steam (Mlbs) at PABT and WTC respectively.

### 6.2.2 Method

The attributes of the Con Edison 59<sup>th</sup> Street Generating Station served as the basis for calculating the emission factors associated with Con Edison steam purchases. For each pollutant, the emission factor was assessed as the ratio of station's emissions to its energy intake. The station's primary energy consumption was available from EPA's Facility Information on GreenHouse Gases Tool (FLIGHT) database (EPA 2017b). Plant emissions were retrieved from multiple sources. GHG emissions were retrieved from the FLIGHT database, while NO<sub>x</sub> emissions came from EPA's Air Market Division Database (EPA 2017a). PM emissions were calculated using AP-42 emission factors for oil and natural gas fired boilers (EPA 1995). Table 6-3: Con Edison Steam Emission Factors presents the emission factors for purchased steam as provided by Con Edison.

<b>Table 6-3: Con Edison Steam Emission Factors</b>							
<b>Metric</b>	<b>CO<sub>2</sub></b>	<b>CH<sub>4</sub></b>	<b>N<sub>2</sub>O</b>	<b>SO<sub>2</sub></b>	<b>NO<sub>x</sub></b>	<b>PM<sub>2.5</sub></b>	<b>PM<sub>10</sub></b>
Steam (kg/Mlbs)	66.22	1.42 x 10 <sup>-3</sup>	1.74 x 10 <sup>-4</sup>	3.67 x 10 <sup>-4</sup>	7.13 x 10 <sup>-2</sup>	4.74 x 10 <sup>-3</sup>	4.74 x 10 <sup>-3</sup>

### 6.2.3 Results

Table 6-4: GHG & CAP Emissions from Con Edison Steam Purchases (metric tons) presents GHG and CAP emissions associated with Con Edison purchased steam for PABT and WTC. Total may not add up due to rounding.

<b>Table 6-4: GHG &amp; CAP Emissions from Con Edison Steam Purchases (metric tons)</b>								
<b>Facility</b>	<b>CO<sub>2</sub></b>	<b>CH<sub>4</sub></b>	<b>N<sub>2</sub>O</b>	<b>CO<sub>2</sub>e</b>	<b>SO<sub>2</sub></b>	<b>NO<sub>x</sub></b>	<b>PM<sub>2.5</sub></b>	<b>PM<sub>10</sub></b>

<b>TOTAL</b>	<b>6,375</b>	<b>0.14</b>	<b>0.02</b>	<b>6,383</b>	<b>0.04</b>	<b>6.87</b>	<b>0.46</b>	<b>0.46</b>

Note: Totals may not match the column sums due to rounding.

## **7.0 ENERGY PRODUCTION (SCOPE 3)**

This chapter discusses the emitting activities associated with two power generation plants owned by the Port Authority; namely, the Kennedy International Airport Cogeneration (KIAC) facility located in Queens County, New York, and the Essex County Resource Recovery (ECRR) facility located in Essex County, New Jersey.

### **7.1 KENNEDY INTERNATIONAL AIRPORT COGENERATION**

This section describes how plant-level operational data were used to assess plant-level emissions, as well as the steps taken for distributing these emissions between end users, including the Port Authority, JFK airport tenants, and downstream consumers of KIAC electricity. The Port Authority leases the KIAC facility to KIAC Partners, a partnership wholly owned by the Calpine Corporation, pursuant to a long-term lease agreement expiring on January 31, 2020. KIAC Partners is responsible for the operation and maintenance of the KIAC facility. The current business model features an energy purchase agreement with the Port Authority for electricity and thermal energy needs of the JFK airport in which excess electricity is sold to market and excess thermal energy is resold to JFK tenants (Port Authority 2014b).

#### **7.1.1 Activity Data**

The KIAC facility is a combined-cycle power plant equipped with two identical gas combustion turbines and one steam generator fed by two heat recovery steam generators (HRSGs). The gas combustion turbines and HRSGs run on natural gas and jet “A” fuel. The KIAC facility produces both electricity and thermal energy.

The plant operator, Calpine Corporation, provided all necessary information to assess plant-specific electricity and thermal production metrics in terms of mass of air pollutants over electricity or thermal energy sold. Key operational data included fuel input, electric power output, and thermal production output (Calpine 2017).

#### **7.1.2 Plant Emissions Method**

This analysis used a fuel-based methodology, whereby the natural gas and jet “A” fuel inputs were converted to emissions using default emission factors. The CO<sub>2</sub> emission factors are fuel specific to natural gas and jet “A” fuel, and the N<sub>2</sub>O and CH<sub>4</sub> emission factors are fuel type and power generation technology specific (e.g., combined cycle, natural gas combustion). PM emission factors were obtained from EPA AP-42, Chapter 3 Table 3.1-2a (EPA 1995), where the industry-average emission rate is expressed in terms of PM mass per unit of heat input. Note that PM<sub>10</sub> and PM<sub>2.5</sub> emissions were assumed to be the same as a conservative measure. Emission factors used in the assessment are presented in Table 7-1 and Table 7-2. NO<sub>x</sub> and SO<sub>2</sub> emissions were obtained from environmental compliance public records (EPA 2017a).

<b>Table 7-1: Emission Factors for Natural Gas Combustion at Combined Cycle Power Plant</b>			
<b>Pollutant</b>	<b>Value</b>	<b>Units</b>	<b>Source</b>
CO <sub>2</sub>	53.06	kg/MMBtu	TCR 2017, Table 12.1

PM <sub>2.5</sub>	0.01	lbs/MMBtu	EPA 1995
PM <sub>10</sub>	0.01	lbs/MMBtu	EPA 1995

### 7.1.3 Electricity and Thermal Emission Factors

KIAC supplies electricity and thermal (heating and cooling) energy for the benefit of Port Authority operations and tenants. Best carbon accounting practices require that emissions from a combined heat and power (CHP) plant be allocated to end-users by means of electricity, heating, and cooling-specific emission factors. These emission factors were calculated first by allocating plant emissions in accordance with the specification of TCR (see Figure 7-1) to each useful energy output of the KIAC plant, and then dividing allocated emissions by the corresponding amount of useful energy. The resulting emission factors are presented in Table 7-3 for each useful energy output, namely electricity, heating, and cooling. These plant emission factors were used to estimate Port Authority indirect emissions from electricity and thermal energy consumption from KIAC, as described in Sections 5.1.2 and 6.1.2, respectively.

<b>Equation 12k</b>	<b>Allocating CHP Emissions to Steam and Electricity</b>
Step 1:	$E_H = (H \div e_H) \div [(H \div e_H) + (P \div e_P)] \times E_T$
Step 2:	$E_P = E_T - E_H$
Where:	<p><math>E_H</math> = Emissions allocated to steam production  <math>H</math> = Total steam (or heat) output (MMBtu)  <math>e_H</math> = Efficiency of steam (or heat) production  <math>P</math> = Total electricity output (MMBtu)  <math>e_P</math> = Efficiency of electricity generation  <math>E_T</math> = Total direct emissions of the CHP system  <math>E_P</math> = Emissions allocated to electricity production</p>

Source: TCR 2013a.

## 7.2 ESSEX COUNTY RESOURCE RECOVERY FACILITY

At the ECRR facility, GHG and CAP emissions result from energy recovery activities, including the combustion of MSW as the primary source of energy for electricity generation, and diesel fuel combustion as an auxiliary energy source. This emitting activity includes emissions from electricity generation and excludes emissions associated with hauling and tipping of waste. The ECRR facility consists of three mass-fired boilers with two turbine generators.

### 7.2.1 Method

The ECRR facility is subject to mandatory reporting of GHG and CAP emissions. For that reason, emissions for the ECRR facility were compiled from public sources.

Under EPA's Greenhouse Gas Reporting Program (GGRP), defined under Title 40 of the Code of Federal Regulations (40 CFR) Part 98, large electricity producers must report general combustion CO<sub>2</sub> emissions as well as biogenic CO<sub>2</sub>, CH<sub>4</sub>, and N<sub>2</sub>O emissions. The ECRR facility is subject to 40 CFR Part 98 reporting and annually submits to EPA quality-assured data from continuous emission monitoring systems (CEMSs). Part 98 reporting data

were accessed through EPA's Facility Level Information on GreenHouse Gases Tool (FLIGHT) database (EPA 2017b), for the "Covanta Essex Company" profile. A CEMS is the total equipment necessary for the determination of an emission rate using pollutant analyzer measurements at the stack. Emission estimates using CEMS are verified by EPA and meet the highest standard of accuracy under the GGRP. GHG emissions, heat rating, and hours of operation data collected under EPA's GGRP served as the basis of the GHG analysis presented in this chapter (EPA 2017b).

Additionally, the ECRR facility is subject to New Jersey's Emission Statement rule (N.J.A.C. 7:27-21) and annually reports to the New Jersey Department of Environmental Protection criteria pollutant emissions data. Criteria pollutant emissions for NO<sub>x</sub>, SO<sub>2</sub>, PM<sub>10</sub>, and PM<sub>2.5</sub> were retrieved from the New Jersey Open Public Records Act Department of Environmental Protection Data Miner database (New Jersey 2017).

### 7.2.2 Results

Anthropogenic GHG emission from the ECRR facility are presented in Table 7-6. The ECRR facility uses MSW as primary fuel and No. 2 fuel oil as an auxiliary fuel. Emissions come almost exclusively from MSW combustion, with less than 0.8 percent resulting from No. 2 fuel oil combustion. The ECRR facility also had 499,459 tCO<sub>2</sub> of biogenic emissions from the combustion of organic materials in MSW. CAP emission estimates are summarized in Table 7-7.

<b>Table 7-6: GHG Emissions from the Essex County Resource Recovery Facility (metric tons)</b>

## 8.0 AIRCRAFT (SCOPE 3)

The Port Authority manages and operates the following airports:

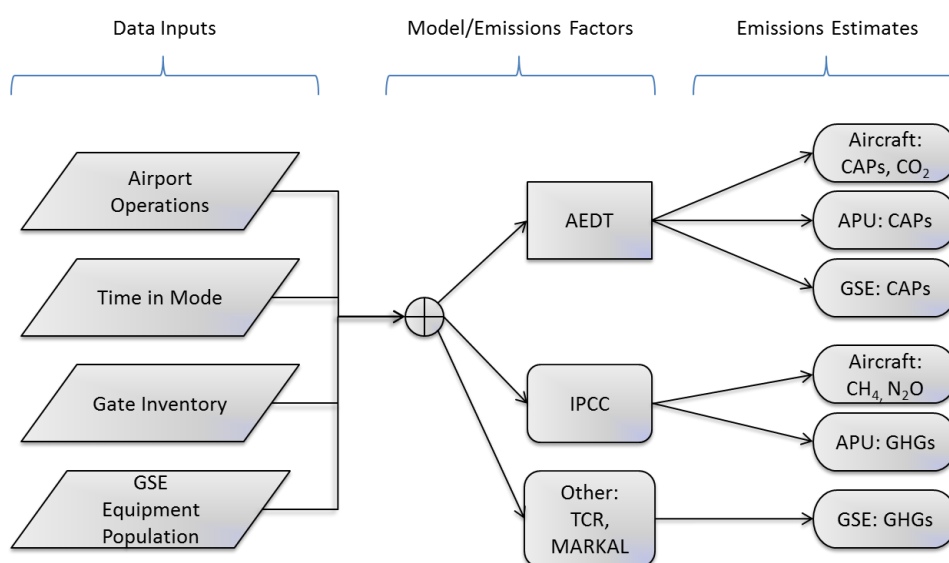

- John F. Kennedy International Airport (JFK);
- Newark Liberty International Airport (EWR);
- LaGuardia Airport (LGA);
- Stewart International Airport (SWF); and
- Teterboro Airport (TEB).

JFK has been recognized for decades as the premier U.S. gateway for passengers and cargo. JFK is the busiest airport in the New York City metropolitan area. In 2016, the airport handled a record 58.9 million passengers, and more than 1.26 million tons of cargo. About 85 airlines operate out of the airport, serving about 165 nonstop destinations. EWR is among the busiest North American and international airports. In 2016, about 40.3 million passengers used the airport, an all-time record. About 33 airlines operate out of the airport, serving more than 166 nonstop destinations. LGA is one of the nation's leading domestic gateways for business travel and is the primary business/ short-haul airport for New York City. LGA set a new all-time record in 2016 with more than 29.8 million passengers. Ten airlines serve 73 nonstop destinations at LGA. SWF is a convenient alternative to the New York/New Jersey metropolitan region's airports. Several commercial and charter airlines operate at the airport, offering direct access to a number of major U.S. hubs. Stewart handled about 275,000 passengers and more than 22,000 tons of cargo in 2016. TEB, designated as a reliever airport for general aviation in the New York-New Jersey region, is a 24-hour public-use facility. The airport does not permit scheduled commercial operations and prohibits aircraft with operating weights in excess of 100,000 pounds (Port Authority 2017b).

This chapter covers emitting activities within the organizational boundary of the Port Authority associated with the operation of aircraft, auxiliary power units (APU), and ground support equipment (GSE). While the Port Authority maintains financial control over the airport's infrastructure, it does not have operational control over aircraft movements or GSE operations. For that reason, greenhouse emissions reflected in this chapter correspond to tenant emissions (i.e., scope 3 emissions) over which the Port Authority has no operational control.

The primary modeling tool for assessing aircraft and GSE emissions is the Federal Aviation Administration's (FAA's) Aviation Environmental Design Tool (AEDT), version 2d, released September 2017 (AEDT 2017). This model replaces FAA's Emission and Dispersion Modeling System (EDMS) model, which was used in developing all Port Authority aviation emission inventories prior to 2014.

AEDT models emissions as a function of the volume of operations (i.e., annual number of arrivals and departures) and aircraft fleet mix at each airport. Additional model inputs include annual average taxi in/out times, extent of gate electrification with preconditioned air (PCA) supply, and ground support equipment profiles. Because AEDT provides partial GHG emissions information limited to CO<sub>2</sub> emissions for aircraft, most emission factors for GHGs of interest, such as CH<sub>4</sub> and N<sub>2</sub>O were developed using Intergovernmental Panel on Climate Change (IPCC) guidance. Supplemental emission factors were taken from The Climate Registry's General Reporting Protocol and EPA's MARKet ALlocation (MARKAL) database to improve the estimate for GSE. The general structure of the emissions inventory in terms of activity data, methods and emissions factor sources utilized to develop emissions estimates is presented in Figure 8-1. Schematic of the

**Figure 8-1. Schematic of the Aircraft, APU and GSE Inventory**

## 8.1 AIRCRAFT MOVEMENTS AND AUXILIARY POWER UNITS

For aircraft emissions, the inventory boundary encompasses aircraft operations that FAA defines as itinerant and local. Itinerant operations are operations performed by an aircraft that lands at the airport, arriving from outside the airport area, or departs from the airport leaving the airport area. Local operations are those operations performed by aircraft that remain in the local traffic pattern, execute simulated instrument approaches or low passes at the airport, and the operations to or from the airport and a designated practice area within a 20-mile radius of the tower (FAA 2012). Additionally, the inventory boundary includes aircraft emissions associated with the following six times-in-mode that together constitute a Landing and Take-Off (LTO) cycle.

1. Approach – portion of the flight from the time that the aircraft reaches the mixing height (approximately 3,000 feet altitude) to touchdown on the runway.
2. Taxi In – the landing ground roll segment from touchdown to the runway exit of an arriving aircraft and the taxiing from the runway exit to a gate.
3. Startup – aircraft main engine startup emissions quantified for aircraft with ICAO certified engines.
4. Taxi Out – the taxiing from the gate to a runway end.
5. Takeoff – the portion from the start of the ground roll on the runway, through wheels off, and the airborne portion of the ascent up to cutback during which the aircraft operates at maximum thrust.
6. Climb out – the portion from engine cutback to the mixing height.

This chapter also covers emissions from the use of auxiliary power units APUs. These are on-board generators that provide electrical power to the aircraft while its engines are shut down. Excluded from this chapter are aircraft cruising emissions (i.e., emissions generated above mixing height between departure and arrival airports) because the study focuses on local emissions.

### 8.1.1 Activity Data

Operations data by aircraft type were provided for the five airports by the Aviation department (Port Authority 2017h). The data set for each airport contains the number of arrivals and departures grouped by ICAO aircraft code. As a quality assurance/quality control (QA/QC) measure, total operations for each airport are normalized using airport operations data as reported in the FAA Air Traffic Activity Data System (ATADS) (FAA 2017). For example, the Aviation department recorded 422,582 operations in 2016 for EWR. On the other hand, the ATADS database shows 431,214 operations (FAA 2017). For consistency with FAA records, operations are adjusted to match the ATADS database. Total 2016 operations and passenger count by airport are shown in Table 8-1.

<b>Table 8-1: Port Authority Operations and Passenger Traffic by Airport</b>		
<b>Airport</b>	<b>FAA ATADS Operations</b>	<b>Passenger Count <sup>a</sup></b>
JFK	458,707	59,105,513
EWR	431,214	40,563,285
LGA	374,487	29,786,769
SWF	43,851	275,421
TEB	177,606	No Data

<sup>a</sup> Port Authority 2017b

Figure 8-2 below presents a distribution of operations based on aircraft size as measured by their arrival weight. Small aircraft have a weight less than 50,000 pounds, medium aircraft have a weight between 50,000 and 100,000 pounds, and large aircraft have a weight greater than 100,000 pounds. The distribution of operations across the aircraft fleet mix is provided in Appendix B: 2016 Operations By Aircraft Code for each of the five Port Authority airports.

**Figure 8-2. Aircraft Distribution by Size and Airport**

Airport-specific taxi times for 2016 were provided by the Aviation department (Port Authority 2017i) and are displayed in Table 8-2: Average Taxi In and Taxi Out Times by Airport below. For EWR and LGA, these taxi times only include domestic operations by major (non-regional) domestic carriers. For JFK, only total taxi time was available, so that total time was allocated to taxi in and taxi out based on the ratio between taxi in and taxi out seen in 2015 at JFK (Port Authority 2016c).

<b>Table 8-2: Average Taxi In and Taxi Out Times by Airport</b>		
<b>Airport</b>	<b>Taxi In (minutes)</b>	<b>Taxi Out (minutes)</b>
JFK	8:37	24:46
EWR	9:37	20:34
LGA	8:36	27:23
SWF	AEDT Default	
TEB	AEDT Default	

The percentage availability of PCA and gate electrification at each airport in 2016 was provided by the Port Authority. This information was used to postprocess AEDT APU results to reflect the decline of APU utilization with greater availability of PCA and gate electrification at the terminals. This information is summarized in Table 8-3: Gate Electrification and PCA Available at Port Authority Airports.

<b>Table 8-3: Gate Electrification and PCA Available at Port Authority Airports</b>		
<b>Airport</b>	<b>Percentage of gates with gate power (400hz)</b>	<b>Percentage of gates with preconditioned air</b>
JFK	98%	92%
EWR	100%	75%
LGA	95%	47%
SWF	100%	100%
TEB	0%	0%

### 8.1.2 Method

AEDT models emissions as a function of the volume of operations (i.e., annual number of arrivals and departures) by aircraft type, as well as performance parameters, including the duration of each mode of operation (e.g., taxi in and taxi out).

A crosswalk was used to correlate aircraft types between the International Civil Aviation Organization (ICAO) aircraft codes to the AEDT aircraft codes. Operations for which an exact match was not found were distributed proportionately across the correlated aircraft mix to ensure that the sum of operations by AEDT aircraft code is consistent with ATADS. In all cases, more than 85% of all aircraft operations had a matching AEDT aircraft code. In general, this rate is higher at the three larger airports (greater than 95% match for EWR, LGA and JFK), whereas the rate is slightly lower for TEB (86%) and SWF (88%).

AEDT estimates emissions for CO<sub>2</sub>, VOC, CO, NO<sub>x</sub>, SO<sub>x</sub>, PM<sub>10</sub>, and PM<sub>2.5</sub>. Because this study is also interested in CH<sub>4</sub> and N<sub>2</sub>O emissions, these pollutant estimates were prepared using the Tier I methodology found in the 2006 IPCC Guidelines for National Greenhouse Gas Emissions Inventories (IPCC 2006), Volume 2, Chapter 3, Table 3.6.9. The Tier I methodology estimates CH<sub>4</sub> and N<sub>2</sub>O emissions as a function of LTO. IPCC emission factors were correlated to the fleet mix by means of the ICAO designators. Because the IPCC emission factors list is incomplete, there were instances where a match could not be established. Instead, a default CH<sub>4</sub> and N<sub>2</sub>O emission factor was calculated for each airport as the average of emission factors for matching aircraft types at that airport and was applied to the total number of LTOs at that airport. The average aircraft CH<sub>4</sub> and N<sub>2</sub>O emission factors by airport are presented in Table 8-4: Average Aircraft CH<sub>4</sub> and N<sub>2</sub>O Emission Factors.

<b>Table 8-4: Average Aircraft CH<sub>4</sub> and N<sub>2</sub>O Emission Factors</b>			
<b>Airport</b>	<b>CH<sub>4</sub></b>	<b>N<sub>2</sub>O</b>	<b>Unit</b>
JFK	0.110	0.132	kg/LTO
EWR	0.089	0.102	kg/LTO
LGA	0.079	0.099	kg/LTO
SWF	0.106	0.103	kg/LTO
TEB	0.077	0.089	kg/LTO

APUs are most often on-board generators that provide electrical power to the aircraft while its engines are shut down. The on-board APU is, in effect, a small jet engine and the emissions assessment is similar to that of an aircraft engine operating in one power setting only. For a given aircraft, APU emissions are modeled as the product of operations, APU running time, and engine emission factors. APU CAP emissions were modeled in AEDT as a function of operations with default APU assignments by aircraft code. GHG emissions for APUs are not included in AEDT, and therefore were estimated outside of the model. CO<sub>2</sub> emissions were estimated using the CO<sub>2</sub>/SO<sub>2</sub>

stoichiometric ratio as evaluated for aircraft engine emissions. CH<sub>4</sub> and N<sub>2</sub>O emissions were estimated based on the CH<sub>4</sub>/CO<sub>2</sub> and N<sub>2</sub>O/CO<sub>2</sub> airport-wide emission ratios assessed for aircraft engine.

Based on guidance from the Federal Aviation Administration (FAA) Voluntary Airport Low Emissions Program (VALE), 2016 APU estimates were revised downward in cases where PCA and gate electrification are available. When gate power and PCA are both provided to the parked aircraft, APU emissions are eliminated except for the default of 7 minutes needed on average to connect and disconnect gate services. In all other cases, the default APU run time of 26 minutes was applied.

The percentage availability of PCA and gate electrification at each airport is displayed in Table 8-3. In cases where both gate power and PCA are less than 100 percent, the lower of the two figures is used for calculations (for example, JFK is assumed to have 92 percent of gates with both gate power and PCA).

### 8.1.3 Results

Emission estimates from aircraft engines are summarized by airport in Table 8-5: GHG & CAP Emissions from Aircraft by Airport (metric tons). In general, GHG emissions were relatively stable between 2015 and 2016, with JFK CO<sub>2</sub>e emissions declining by 5 percent, and the other four airports showing modest growth. EWR emissions increased by 12 percent, primarily as a result of a 21 percent increase in taxi times and a 3 percent increase in operations.

<b>Airport</b>	<b>CO<sub>2</sub></b>	<b>CH<sub>4</sub></b>	<b>N<sub>2</sub>O</b>	<b>CO<sub>2</sub>e</b>	<b>SO<sub>2</sub></b>	<b>NO<sub>x</sub></b>	<b>PM<sub>2.5</sub></b>	<b>PM<sub>10</sub></b>

<b>TOTAL</b>	<b>1,877,974</b>	<b>68.1</b>	<b>80.8</b>	<b>1,904,446</b>	<b>697</b>	<b>6,846</b>	<b>55.2</b>	<b>55.2</b>

Note: Totals may not match the column sums due to rounding.

APU GHG and CAP emissions are displayed in Table 8-6: GHG & CAP Emissions from APU by Airport (metric tons). These results reflect the effects of PCA and gate electrification where installed, which decreases the demand of running APUs and lowers emissions compared to a scenario without supplied PCA and gate electrification.

## 8.2 GROUND SUPPORT EQUIPMENT

GSE service aircrafts upon arrival and prior to departure from the date. During aircraft arrivals, GSE are used to unload baggage and service the lavatory and cabin. Prior to aircraft departure, GSE are present to load baggage, food and fuel. Additionally, a tug may be used to push or tow the aircraft away from the gate and to the taxiway (AEDT 2017).

### 8.2.1 Activity Data

GSE inventories were provided by the Port Authority (Port Authority 2016c) for the three large international airports (i.e., JFK, EWR and LGA). These inventories are based on airlines' responses to GSE surveys for equipment they operate and served as the primary input for GSE emissions modeling. The inventories provide information about the make-up of the GSE fleet, the number of units by equipment type, and model year (e.g., 2 counts of a 2005 model year, diesel, TUG MA 50 Tractor).

Additionally, a crosswalk was developed to establish a direct correspondence between equipment types as reported by airlines and the equivalent equipment type from the GSE menu in AEDT. This crosswalk enables the assignment of default GSE parameters, most notably the average annual utilization hours per equipment and engine load. It was noted that AEDT does not have an equipment profile for diesel deicers. Because there are a significant number of diesel deicers at Port Authority airports, these emissions were modeled separately, using the equipment profile of the most similar unit in AEDT's GSE menu with regard to horsepower (hp) and load factor (LF).

Because GSE inventorying efforts have not yet been conducted at TEB and SWF, their GSE equipment counts were developed using EDMS default GSE assignments, which correspond to each airport's unique aircraft mix. In general, EDMS assigns a greater number of GSEs and utilization values (i.e., minutes per operation) to large and medium size aircraft than to regional or business jets. Note that EDMS default GSE assignments were used at TEB and SWF because the current version of AEDT does not have an equivalent function. The default assignments for TEB and SWF from EDMS CY2013 were used to create an estimate of what the GSE inventory at these airports is expected to be in 2016. The hours of operation from this 2013 EDMS inventory were then scaled to CY2016 based on the ratio of 2016 to 2013 LTOs and input into AEDT to estimate emissions for CY2016 (FAA 2017).

Appendix C: 2016 Ground Support Equipment Profiles provides a summary GSE profiles and utilization for all five airports.

### 8.2.2 Method

GSE CAP emissions were modeled in AEDT using the activity data described in the Section Activity Data. The GSE module in AEDT is a variation of EPA's NONROAD2008 model, which estimates GSE emissions as a function of equipment type (e.g., aircraft tractor and belt loader), utilization (i.e., hours per year), fuel type (e.g., diesel or gasoline), engine capacity, average load, model year, and emission rates.

<b>Table 8-7: Emissions Ratios Applied to AEDT GSE Output</b>		
<b>Concept</b>	<b>Fuel Type</b>	<b>Ratio Value</b>
CO <sub>2</sub> /SO <sub>2</sub>	Gasoline	4,560
CH <sub>4</sub> /CO <sub>2</sub>	Gasoline	0.000057
N <sub>2</sub> O/CO <sub>2</sub>	Gasoline	0.000025
CO <sub>2</sub> /SO <sub>2</sub>	Diesel	144,199
CH <sub>4</sub> /CO <sub>2</sub>	Diesel	0.000057
N <sub>2</sub> O/CO <sub>2</sub>	Diesel	0.000025
CO <sub>2</sub> /SO <sub>2</sub>	LPG	51,481
CH <sub>4</sub> /CO <sub>2</sub>	LPG	0.000057
N <sub>2</sub> O/CO <sub>2</sub>	LPG	0.000025
CO <sub>2</sub> /SO <sub>2</sub>	CNG	45,268
CH <sub>4</sub> /CO <sub>2</sub>	CNG	0.000057
N <sub>2</sub> O/CO <sub>2</sub>	CNG	0.000025

When available, model year information was specified as a parameter in AEDT. In all other cases, a default model year value was applied based on the EPA-derived national fleet average age for a given equipment type.

AEDT generates estimates of criteria pollutants associated with GSE, but does not provide estimates of CO<sub>2</sub>, CH<sub>4</sub> or N<sub>2</sub>O. For that reason, GHG emissions were assessed based on the quantitative relationship (i.e., stoichiometry) between SO<sub>2</sub> emissions and CO<sub>2</sub> emissions. This relationship was used because both SO<sub>2</sub> and CO<sub>2</sub> emissions are directly proportional to the mass of fuel combusted. That is, for any given concentration of sulfur, the CO<sub>2</sub>/SO<sub>2</sub> ratio is constant. Then, CH<sub>4</sub>/CO<sub>2</sub> and N<sub>2</sub>O/CO<sub>2</sub> emission ratios—derived from standard fuel-based emission factors—were applied to CO<sub>2</sub> emissions to determine CH<sub>4</sub> and N<sub>2</sub>O emissions.

The SO<sub>2</sub> emission factors used in AEDT are based on NONROAD 2008, which assumes a gasoline sulfur content of 339 ppm. Because the current gasoline sulfur limit is 30 ppm (EPA 2016), gasoline SO<sub>2</sub> emissions modeled in AEDT were multiplied by a factor of 0.09 to properly reflect the current federal gasoline sulfur standard. At 339 ppm, the CO<sub>2</sub>/SO<sub>2</sub> ratio for gasoline equals 4,560. This ratio was applied to the AEDT unadjusted SO<sub>2</sub> gasoline emissions to estimate CO<sub>2</sub>. At the current diesel sulfur concentration of 11 ppm, the CO<sub>2</sub>/SO<sub>2</sub> ratio for diesel combustion equals 144,199 (EPA 2009b). The CO<sub>2</sub>/SO<sub>2</sub> ratio for other fuels (e.g., liquefied petroleum gas, LPG) was derived from EPA's MARKAL model (Pechan 2010) and applied to AEDT SO<sub>x</sub> estimates in order to calculate

CO<sub>2</sub> emissions<sup>3</sup>. Then, CH<sub>4</sub>/CO<sub>2</sub> and N<sub>2</sub>O/CO<sub>2</sub> ratios—derived from standard non-highway vehicle emission factors—were applied to CO<sub>2</sub> emissions in order to determine CH<sub>4</sub> and N<sub>2</sub>O emissions (TCR 2017). All GHG emissions ratios applied in developing GSE emissions are shown in Table 8-7: Emissions Ratios Applied to AEDT GSE Output.

### 8.2.3 Results

Table 8-8: GHG & CAP Emissions from GSE by Airport (metric tons) shows the GHG and CAP emission estimates for GSE by airport.

<b>Table 8-8: GHG &amp; CAP Emissions from GSE by Airport (metric tons)</b>

Note: Totals may not match the column sums due to rounding.

<sup>3</sup> Sulfur oxides (SO<sub>x</sub>) is the term referring to a set of compounds of sulfur and oxygen, of which sulfur dioxide (SO<sub>2</sub>) is the predominant form found in the lower atmosphere. When estimating GSE CO<sub>2</sub> emissions, it was assumed that all SO<sub>x</sub> was in the form of SO<sub>2</sub>.

## 9.0 ATTRACTED TRAVEL (SCOPE 3)

Attracted travel refers to customer motorized travel to access Port Authority infrastructure and includes a range of activities. For the EY2016, attracted travel assessment were limited to Aviation department activities, namely, airport passenger and air cargo attracted travel.

### 9.1 AIRPORT PASSENGERS

For attracted travel related to passenger access to airports (excluding cargo-related vehicles), the established boundary includes the trip to or from the airport up to a maximum of 100 miles. This boundary was developed based on the trip origin data received from the Port Authority's Aviation department (Port Authority 2017f). The airport passengers portion includes emissions associated with all vehicle trips that are attracted by airport facilities. Vehicle types (also referred to as travel mode) include privately-owned vehicles, taxis, buses, rental cars, limousines, vans, shuttle buses, public buses, Uber/Lyft, parking at the airport, dropped off by personal car, and off-airport parking. Vehicle miles traveled (VMTs) for the airport facilities were calculated by mode, and for the trip to or from the airport.

#### 9.1.1 Activity Data

The data inputs to the attracted travel analysis were the 2016 passenger survey data (Port Authority 2017f), which provided the passenger origin/destination information, the 2016 total passenger data (Port Authority 2017b) for information on the total number of passengers, and data on average travel party size (Excellent et al. 2008; Airlink et al. 2008; Port Authority 2017e).

The 2016 total passenger data were adjusted to exclude in-transit passengers (passengers with a connection in a Port Authority airport prior to their destination) because these passengers do not induce attracted travel. The percentage of passengers on connecting flights by airport (Port Authority 2017g) used to adjust total passenger volumes is presented in Table 9-1: Percentage of Total Passengers on Connecting Flights.

<b>Table 9-1: Percentage of Total Passengers on Connecting Flights</b>	
<b>Airport</b>	<b>Percent of Passengers</b>
JFK	22%
EWR	32%
LGA	17%
SWF	2%
TEB	0%

Passengers are assumed to take a one-way trip (either to or from the airport) to their destination. For JFK, EWR and LGA, personal car trips were divided between those where passengers were dropped off at an airport and those

where passengers parked at an airport. Trips where the passenger parked at the airport use a one-way distance, whereas drop-offs use the round-trip distance. For SWF, there was no subdivision of the personal car category, and therefore, passengers who are arriving/departing via personal car were assumed to be a pickup/drop off and therefore the round-trip distance is used. This assumption is made to be more conservative, and because pickup/drop-off is more common than parking at the airport at JFK, EWR and LGA.

### 9.1.2 Method

For each airport, except TEB, the number of passengers was allocated by travel mode and trip origin prior to estimating the number of vehicles. The number of vehicles by travel mode and trip origin was estimated using the number of passengers, trip distributions by travel mode to each passenger origin, average travel party size, and estimated distance traveled. Trip distributions by mode to each passenger origin were obtained from the Port Authority's Aviation department (Port Authority 2017f). Information on the estimated trip distances and average travel party size are listed in Table 9-2: One-Way Travel Distances Associated with Airport Facilities and Table 9-3: Average Travel Party Size by Travel Mode and Facility, respectively.

Table 9-2: One-Way Travel Distances Associated with Airport Facilities lists the trip origins for airport attracted travel with the corresponding estimated one-way travel distances by airport, except for TEB. Trip origin and travel mode data were not available for TEB. The methodologies used to estimate attracted travel emissions for TEB are discussed in a separate section later in this chapter. Distances reported in Table 9-2: One-Way Travel Distances Associated with Airport Facilities were estimated using Google Maps roadway trip lengths. The surrogate location associated with each origin/destination represents the most populous locality within the county or jurisdiction.

<b>Table 9-2: One-Way Travel Distances Associated with Airport Facilities</b>

<sup>b</sup> Excellent et al. 2008.

<sup>c</sup> Airlink et al. 2008.

The trip distance data presented in Table 9-2 and the average party size data, which are shown in Table 9-3, along with the trip distribution data, were applied to develop the total VMT accumulated due to airport attracted travel. The methodology for estimating VMT is consistent for private cars, limousines, chartered buses, hotel/motel/off-airport shuttle buses, Uber/Lyft, parking at airport, and van services vehicle categories, and is estimated using Equation 9-1. Airport drop-offs also use this methodology, but the trip length is the round-trip distance, since the drop-off vehicle would need to return home in that single trip.

$$VMT = \frac{N \times \%D}{P} \times L \quad (9-1)$$

Where:

$VMT$  = vehicle miles traveled

$N$  = number of passengers

$\%D$  = percent distribution by trip origin and travel mode

$P$  = travel party size or vehicle occupancy in case of buses and shuttles

$L$  = trip length (one-way, miles)

The calculation of VMT for taxis and rental cars are based on the number of vehicle trips rather than the number of passengers, since the number of these vehicles is known. For taxis servicing JFK, LGA and EWR, the number of taxis dispatched was provided by Port Authority (Port Authority 2017c), and data on total rental car transactions for these airports were also provided by the Port Authority (Port Authority 2017d). These numbers of vehicle trips are allocated by trip origin/destination utilizing the percentage of airport passengers by trip origin/destination. The number of vehicle trips is then multiplied by the one-way trip distance for each origin/destination location to estimate rental car or taxi VMT. Taxi and rental car transactions data from SWF were not available, so VMT from taxis and rental cars at SWF are estimated like other travel modes. Because no vehicle travel attraction statistics

were available for TEB, based on the types of flights that use TEB, the number of passengers at TEB was estimated as the number of aircraft movements (Port Authority 2017b). TEB attracted travel VMT was estimated assuming an average trip length of 16.2 miles, based on the distance from TEB to Manhattan, with all trips assigned to personal cars at a vehicle occupancy of 1.0.

Once VMT estimates were developed for all attracted travel modes, VMT was summed by facility and mode. Emission factors for attracted travel at airports were calculated using EPA's MOVES model (EPA 2014a) based on input data for the ten New York metropolitan counties (NYMTC 2016). For personal vehicle travel (personal car, rental car, taxi, limo/town car, off-airport parking), the emission factors were based on the weighted average of the MOVES passenger car, passenger truck, and motorcycle vehicle types over the 10 counties. Emission factors for shared-ride van and hotel/motel shuttle van were based on the 10-county weighted average small/medium truck emission factors. Emission factors for public/city bus and airport/charter/tour bus were based on the 10-county weighted average transit bus emission factors. Emissions estimates for all pollutants were developed by multiplying VMT by the corresponding emission factors (in grams per mile).

Cold-start emissions associated with the startup of a cooled vehicle engine were estimated for the following travel modes: personal car, dropped off via personal car, on-airport parkers, rental cars, and off-airport parking. Vehicle emissions for this category were calculated by multiplying the number of vehicle trips by the corresponding weighted cold-start emission factor for each vehicle type, assuming one cold start per trip. Total vehicle trips were estimated by dividing the total number of passengers for each affected travel mode by the vehicle occupancy for that mode for each airport/travel mode combination. The exception was for rental cars, where vehicle trips were assumed to be equivalent to the number of rental car transactions. The cold-start emission factors (in grams per start) by vehicle type were derived from the EPA MOVES model (EPA 2014a).

### **9.1.3 Results**

Total airport attracted travel GHG emission estimates are displayed in Table 9-4 below. Carbon dioxide accounted for more than 99% of all attracted travel CO<sub>2</sub>e emissions. Figure 9-1 shows the CO<sub>2</sub> emissions broken down by both travel mode and airport. The travel modes are simplified into four broad categories: Personal Car (including on airport parking and drop-offs), rental cars, taxi/limo/Uber/Lyft, and Other (including buses, shuttle vans and off-airport parking). Total GHG and CAP emission estimates are broken down by airport, as shown in Table 9-5. JFK airport has the most GHG and CAP emissions, although EWR and LGA also account for a significant portion of the total.

<b>Table 9-4: Airport Passenger Attracted Travel GHG Emissions by Mode (metric tons)</b>

Note: Totals may not match the column sums due to rounding.

<sup>4</sup> The Personal Car total is only for SWF and TEB, as this broad category is not used at EWR, JFK and LGA.

## 9.2 AIR CARGO

In addition to direct passenger service, Port Authority airports handle air cargo. The movement of air cargo to and from the air terminals induce vehicular traffic near the airports. The boundary is defined as the roadway distance between the airport and the first access/egress route as shown in Figure 9-2. Attracted Travel Air Cargo Boundary for JFK.

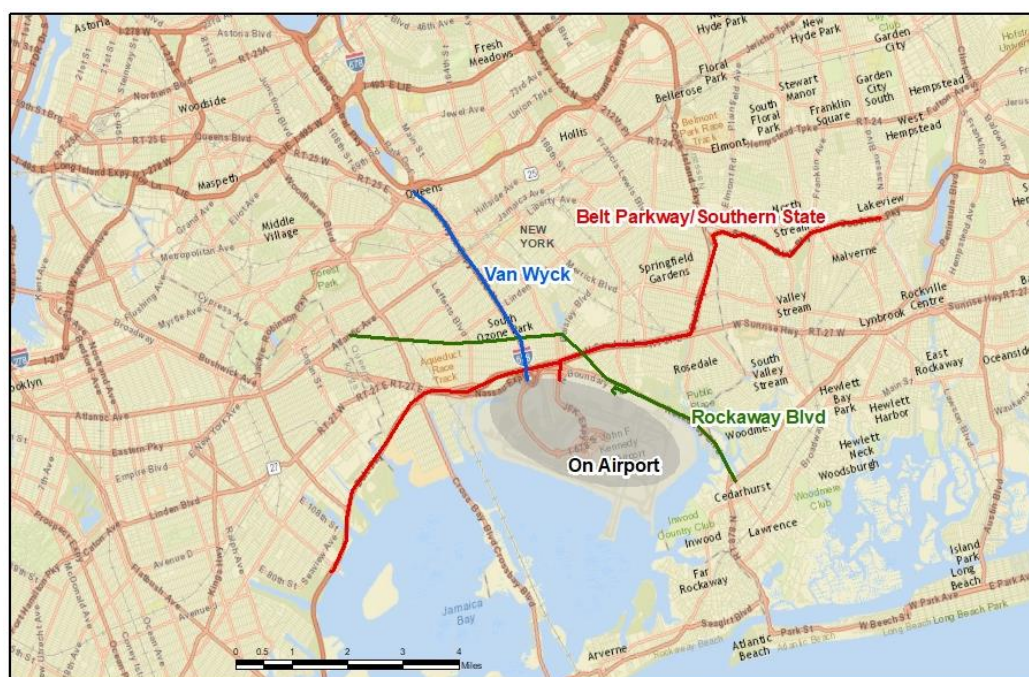

Figure 9-2. Attracted Travel Air Cargo Boundary for JFK

### 9.2.1 Activity Data

The primary data source for estimating attracted travel emissions from cargo shipments at the airports is a 2002 air cargo truck movement study for JFK (URS 2002). This provides data detailing cargo trips by route and vehicle type and is used as a surrogate for cargo shipping at all Port Authority airports.

### 9.2.2 Method

JFK VMT for cargo-related travel was derived by multiplying the number of cargo trips by the estimated trip length of the access and egress routes obtained from the air cargo truck movement study conducted for JFK airport (URS 2002). Trip length by origin was estimated using Google Maps (see Table 9-6).

<b>Table 9-6: One-Way Travel Distance at JFK Airport for Cargo Travel</b>	
<b>Origin/Destination</b>	<b>Miles to/from</b>
Van Wyck	5.1
On Airport	6.7
Rockway Blvd	2.8
Belt Parkway/Southern State	8.2
Other Routes	5.7

Note: Only passenger vehicles are permitted on the Belt Parkway/Southern State Parkway. Therefore, only cargo trips using cars or mini-vans were allocated to this route.

Source: Google Maps Average distance based on Van Wyck, On Airport, Rockaway Blvd., and Belt Parkway/Southern State trip length.

The number of cargo trips at JFK in 2016 was estimated by scaling the number of trips estimated from the 2002 study by vehicle type based on the ratio of 2016 to 2002 freight cargo at JFK (Port Authority 2006; Port Authority 2017b). The resulting 2016 cargo VMT for JFK by vehicle type was then scaled to LGA, EWR and SWF airports using the 2016 ratio of cargo tons from JFK to the cargo tons at LGA, EWR and SWF airports (Port Authority 2017b). EY2016 air cargo tonnage by airport is displayed in Table 9-7: Air Cargo Tonnage by Airport below.

<b>Table 9-7: Air Cargo Tonnage by Airport</b>	
<b>Airport</b>	<b>Annual Cargo Tonnage</b>
JFK	1,315,385
EWR	746,771
LGA	7,586
SWF	18,729
TEB	0
<b>TOTAL</b>	<b>2,088,471</b>

Note: Totals may not match the column sums due to rounding.

GHG and CAP g/mi and g/start emission factors come from EPA's MOVES model (EPA 2014a). There are three different vehicle types included: light duty vehicles, small trucks (such as single unit trucks and 3 and 4 axle tractor trailers) and large trucks (5 and 6 axle tractor trailers). VMT was divided between these vehicle types based on the results of the JFK freight cargo survey (URS 2002). This analysis assumes a roundtrip VMT, and two starts per trip.

### 9.2.3 Results

The GHG and CAP emission estimates from cargo trucks by airport are summarized in Table 9-8: GHG & CAP Emissions from Air Cargo Attracted Travel by Airport (metric tons) below. JFK accounts for the majority of emissions from cargo shipments. TEB has no cargo shipments, and LGA and SWF have only a small amount.

<b>Table 9-8: GHG &amp; CAP Emissions from Air Cargo Attracted Travel by Airport (metric tons)</b>								
<b>Airport</b>	<b>CO<sub>2</sub>e</b>	<b>CO<sub>2</sub></b>	<b>CH<sub>4</sub></b>	<b>N<sub>2</sub>O</b>	<b>SO<sub>2</sub></b>	<b>NO<sub>x</sub></b>	<b>PM<sub>2.5</sub></b>	<b>PM<sub>10</sub></b>
JFK	36,014	35,798	1.5	0.6	0.5	79.3	4.5	9.8

<b>TOTAL</b>	<b>57,181</b>	<b>56,837</b>	<b>2.3</b>	<b>0.9</b>	<b>0.8</b>	<b>125.8</b>	<b>7.2</b>	<b>15.5</b>

Note: Totals may not match the column sums due to rounding.

## 10.0 MOBILE COMBUSTION (SCOPE 3)

### 10.1 SHADOW FLEET

The shadow fleet consists of vehicles that are owned by the Port Authority but are operated on a day-to-day basis by contractors. Because they are not operated by the Port Authority directly, they do not fall within the purview of the CAD (discussed in Chapter 3.0) and are therefore considered scope 3 sources. In EY2016, only Shadow Fleet emissions associated with the Aviation department were assessed to support carbon management initiatives at Port Authority airports.

#### 10.1.1 Activity Data

Data on the shadow fleet were provided by the Port Authority (Port Authority 2017j). In 2016, the shadow fleet consisted of fuel trucks and shuttle buses at JFK, EWR and LGA, as well as a few vehicles at SWF and TEB.

#### 10.1.2 Method

Port Authority provided diesel and gasoline fuel consumption from the shadow fleet. These were then multiplied by the appropriate TCR emission factors to estimate GHG emissions and MARKAL emission factors to estimate the criteria pollutants (TCR 2017 and Pechan 2010).

#### 10.1.3 Results

GHG and CAP emission estimates are summarized by airport in Table 10-1 below. The majority of shadow fleet emissions come from shuttle buses and fuel trucks at JFK and EWR.

<b>Airport</b>	<b>CO<sub>2</sub></b>	<b>CH<sub>4</sub></b>	<b>N<sub>2</sub>O</b>	<b>CO<sub>2</sub>e</b>	<b>SO<sub>2</sub></b>	<b>NO<sub>x</sub></b>	<b>PM<sub>2.5</sub></b>	<b>PM<sub>10</sub></b>
JFK	5,323	0.3	0.2	5,389	0.4	39.8	2.3	2.4
EWR	4,571	0.3	0.2	4,633	0.3	38.4	2.0	2.1
LGA	2,577	0.2	0.1	2,609	0.1	26.9	0.8	0.8
SWF	693	0.0	0.0	702	0.1	2.3	0.5	0.6
TEB	158	0.0	0.0	159	0.0	0.3	0.1	0.1
<b>TOTAL</b>	<b>13,321</b>	<b>0.8</b>	<b>0.5</b>	<b>13,492</b>	<b>1.0</b>	<b>107.8</b>	<b>5.6</b>	<b>6.0</b>

Note: Totals may not match the column sums due to rounding.

## 11.0 TENANT ENERGY CONSUMPTION (SCOPE 3)

Chapter 11 discusses tenant energy consumption and emissions assessments for the Aviation department. Tenants include airlines, airport concessions, fixed-base operators, and the AirTrain (JFK and Newark) systems operated by Bombardier Transportation. The assessment of tenant energy consumption covers three commodities: electricity, natural gas, and thermal energy.

### 11.1 BUILDINGS

#### 11.1.1 Electricity

Building energy consumption was either compiled from metered electricity consumption statements or assessed from the share of building space corresponding to tenant occupancy. Table 11-1 presents a summary of tenant electricity consumption in 2016.

<b>Table 11-1: Tenant Electricity Consumption by Airport</b>	
<b>Airport</b>	<b>Electricity Usage (MWh)</b>
EWR	85,654
JFK	262,019
LGA	72,403
SWF	10,735
TEB	8,097
<b>TOTAL</b>	<b>438,899</b>

Note: Totals may not match the column sums due to rounding.

The Port Authority sub-bills tenants for their electricity consumption at JFK and LGA, so metered electricity consumption informed the assessments at these two airports. For other airports, electricity consumption was estimated based on tenant building occupancy. Electricity consumption emissions were calculated as the product of energy consumption ( $C$ ) and emission per unit of energy consumed for any given pollutant (i.e., the emission factor,  $EF_i$ ), as shown in Equation 11-1. The GHG and CAP emission factors utilized with Equation 11-1 correspond to those used for the estimation of scope 2 purchased electricity emissions and listed on Table 5-2: Electricity Consumption GHG Emission Factors and Table 5-3: Electricity Consumption CAP Emission Factors.

$$Emissions = C \times EF_i \quad (11-1)$$

Where:

$C$  = consumption of electricity (kWh)

$EF_i$  = electricity emission factor for pollutant  $i$  (kg pollutant/kWh)

$i$  = GHG or CAP pollutant

At EWR, SWF and TEB, tenant electricity consumption was assessed as the product of tenant occupied space, energy consumption intensity, and the fraction of energy consumption attributable to electricity consumption. This method is presented in Equation 11-2. Tenant occupied space was compiled for the purposes of the inventory and is summarized on Table 11-2. The only change between tenant occupancy in 2015 and 2016 was at LGA airport. LGA opened a new Terminal B, and on June 1, 2016, it became tenant space. Therefore, tenant emissions were estimated for this 1.3-million square footage terminal for seven months of the year (Port Authority 2017k). The values used for energy consumption intensity ( $I_j$ ) and fraction of total energy consumption attributable to electricity usage ( $S_j$ ) are summarized in Table 11-3.

$$C = \left( \sum_j A_j \times I_j \times S_j \right) \times K \quad (11-2)$$

Where:

$C$  = consumption of electricity (kWh)

$A$  = tenant occupancy area specific to building activity  $j$  (square foot)

$I_j$  = total energy consumption intensity for building activity  $j$  (kBtu/square foot)

$S_j$  = share of total energy consumption attributable to electricity usage specific to building activity  $j$  (unitless)

$K$  = conversion factor from kBtu to kWh

<b>Table 11-2: Tenant Occupancy by Airport (square foot)</b>

### 11.1.2. Natural Gas

The tenant emissions from natural gas consumption were estimated based on the amount of space occupied by tenants in Port Authority-owned facilities. Table 11-2 summarizes tenant occupancy by building activity and airport. Note that at JFK, heating is also supplied in the form of thermal energy from KIAC, consequently, only JFK tenants who are not serviced by KIAC are included in the tenant natural gas consumption assessment.

Natural gas consumption was assessed as the product of tenant occupancy in terms of square footage, the energy consumption intensity per unit area of occupied space, and the fraction of energy consumption attributable to natural gas consumption (EIA 2003). This methodology assumes that energy use not attributable to electricity consumption pertains to natural gas consumption. This assumption is informed by the energy supply profile of Port Authority facilities where the Port Authority has operational control. The methodology is summarized in Equation 11-3. The values used for energy consumption intensity ( $I_j$ ) and share of total energy consumption attributable to electricity usage ( $S_j$ ) are listed in Table 11-3.

$$G = (\sum_j A_j \times I_j \times [1 - S_j]) \times L \quad (11-3)$$

Where:

$G$  = consumption of natural gas (therms)

$A$  = tenant occupancy area specific to building activity  $j$  (square foot)

$I_j$  = total energy consumption intensity for building activity  $j$  (kBtu/square foot)

$S_j$  = share of total energy consumption attributable to electricity usage specific to building activity  $j$  (unitless)

$L$  = conversion factor from kBtu to therm

The GHG and CAP emission factors utilized with Equation 11-3 correspond to those used for the estimation of scope 1 stationary combustion emissions and listed on Table 2-2: Stationary Combustion GHG Emission Factors and Table 2-3: Stationary Combustion CAP Emission Factors. Table 11-5 shows the GHG and CAP emissions estimates from natural gas broken down by facility.

<b>Table 11-5: GHG &amp; CAP Emissions from Tenant Natural Gas Consumption in Buildings (metric tons)</b>

Note: Totals may not match the column sums due to rounding.

### 11.1.3. Thermal

JFK is the only location where tenant thermal energy consumption occurs for heating and cooling applications. Tenant thermal energy consumption information was available from Port Authority sub-billing records.

Emissions from thermal energy consumption were estimated as the product of energy consumption and the pollutant intensity of the thermal energy delivered (i.e., the emission factor). The emission factors are specific to the KIAC facility, which is the supplier of thermal energy. The derivation of these emission factors is discussed in detail in Chapter 7 (see Table 7-3: KIAC Electricity and Thermal Emission Factors by Pollutant). These emission factors are shown in Table 7-3: KIAC Electricity and Thermal Emission Factors by Pollutant.

Port Authority records indicate that there were nearly 128,000 MMBtu of thermal heating and close to 223,000 MMBtu of thermal cooling consumed by JFK tenants. Associated GHG and CAP emissions are shown in Table 11-6.

<b>Table 11-6: GHG &amp; CAP Emissions from Tenant Thermal Consumption in Buildings (metric tons)</b>								
<b>Commodity</b>	<b>CO<sub>2</sub></b>	<b>CH<sub>4</sub></b>	<b>N<sub>2</sub>O</b>	<b>CO<sub>2</sub>e</b>	<b>SO<sub>2</sub></b>	<b>NO<sub>x</sub></b>	<b>PM<sub>2.5</sub></b>	<b>PM<sub>10</sub></b>
KIAC Heating	7,970	0.57	0.14	8,024	1.70	0.04	0.45	0.45
KIAC Cooling	13,888	0.10	0.24	13,982	2.96	0.07	0.78	0.78

## 11.2 RAIL SYSTEMS

The Port Authority owns the AirTrain JFK and AirTrain Newark, but these monorail systems are operated by Bombardier Transportation, thus reported as a scope 3 source. AirTrain JFK operates with service between JFK and two passenger stations in Queens. AirTrain Newark operates with service between EWR and the Northeast Corridor transfer station.

### 11.2.1 Electricity

For electricity consumption of the AirTrain systems, the Port Authority provided consumption data by month for each service location in kWh. Emission estimates were assessed on the basis of metered electricity consumption in combination with the most relevant set of emission factors listed in Table 5-2: Electricity Consumption GHG Emission Factors, and Table 5-3: Electricity Consumption CAP Emission Factors. For AirTrain JFK, two separate sets of emission factors were applied. When electricity was sourced from KIAC, plant-level emission factors were applied. In all other instances, the NYCW emission factors were used for AirTrain JFK. For AirTrain Newark, the RFCE emission factors were applied. Table 11-7 presents GHG and CAP emissions associated with train electricity usage for each system.

<b>Table 11-7: GHG &amp; CAP Emissions from Tenant Electricity Consumption in Rail Systems (metric tons)</b>								
<b>Facility</b>	<b>CO<sub>2</sub></b>	<b>CH<sub>4</sub></b>	<b>N<sub>2</sub>O</b>	<b>CO<sub>2</sub>e</b>	<b>SO<sub>2</sub></b>	<b>NO<sub>x</sub></b>	<b>PM<sub>2.5</sub></b>	<b>PM<sub>10</sub></b>
AirTrain JFK	16,831	1.14	0.26	16,936	3.34	0.88	0.85	0.85
AirTrain Newark	7,203	0.52	0.12	7,252	1.54	0.04	0.41	0.41
<b>TOTAL</b>	<b>24,033</b>	<b>1.66</b>	<b>0.39</b>	<b>24,188</b>	<b>4.87</b>	<b>0.92</b>	<b>1.26</b>	<b>1.26</b>

Note: Totals may not match the column sums due to rounding.

### 11.2.2 Thermal

The Port Authority has a record of thermal energy in the form of heating and cooling delivered by KIAC for consumption at AirTrain JFK. This record of consumption is multiplied by the KIAC-specific emission factors shown in Table 6-1: KIAC Thermal Emission Factors to estimate emissions. Table 11-8 summarizes emissions from thermal energy consumption by AirTrain.

<b>Table 11-8: GHG &amp; CAP Emissions from Tenant Thermal Consumption in Rail Systems (metric tons)</b>

## APPENDIX D: REVISIONS TO THE 2006 BASE YEAR

### 1. Objective

Enable a like-for-like comparison of GHG emissions across the temporal series, and more importantly, against the 2006 base year.

### 2. Attracted Travel Methodology

For this reanalysis, emissions were calculated in a manner as consistent as possible with the most recent methodology used. For most attracted travel categories, the most recent inventory year was 2012, although aviation attracted travel was calculated in the 2016 inventory. These more recent inventories have included the use of MOVES2014a emission factors for all attracted travel categories and pollutants. Unlike the predecessor MOBILE emission factor models, MOVES can provide emission factors for all pollutants of interest as well as emission factors for all activities of interest including vehicle travel, short term idling, extended idling, and starts.

MOVES inputs for this 2006 reanalysis were developed starting with activity data gathered for the original 2006 attracted travel emissions analysis. These data were reformatted as needed for input to MOVES. MOVES inputs that were not available from the original 2006 analysis used MOVES default data specific to the New York metropolitan area. Updated emission factors were calculated for a 2006 calendar year in a manner consistent with the latest attracted travel estimates. Also, where possible, the emission calculation templates from the most recent attracted travel analyses were used as the starting point for the updated 2006 analyses.

For several of the attracted travel categories, additional revisions were necessary to make the 2006 estimates more consistent with the latest estimates. These revisions are described by category below. For attracted travel categories not included here, the only revisions included the change to MOVES-based emission factors.

#### 2.1. Attracted Travel – Aviation

Several significant changes were made to the 2006 activity used in the aviation attracted travel calculations.

- Through passengers (i.e., those continuing on to another flight) were excluded from the passenger counts used in calculating attracted travel emissions.
- The attracted travel trips for most travel modes were calculated as round-trip distances in the original 2006 analysis. This was changed such that only the Personal Car Dropped Off At Airport mode of travel included a round trip distance and all others were calculated as one way trips.
- The 2006 travel data did not include a breakdown of the personal car travel mode by dropped off at airport or parked at airport. Therefore, the 2016 share of these two modes was applied to break out the 2006 personal car travel mode into these two categories, using data specific to each airport.
- Starts from parked cars were no longer calculated separately, as these trip starts are accounted for in the trip starts from personal vehicles parked at the airport.

#### 2.2. Attracted Travel – PATH

The PATH Passenger Travel Study used to estimate the modes of travel by PATH passengers by station was updated from the 2004 study to the 2007 study. Bus travel to and from Journal Square was added to the 2006 PATH attracted travel estimate, consistent with the 2012 calculations.

#### 2.3. Attracted Travel – Tunnels and Bridges

Consistent with later year estimates, the number days of queueing was revised from 260 (weekdays only) to 365 (weekdays and weekends) days per year. Outbound queueing delays were added for the Holland Tunnel, as these were included in the 2012 analysis but were not in the original 2006 analysis.

#### 2.4. Attracted Travel – Ports, Drayage Trucks

The key changes made in the port commerce attracted travel include:

- Updating to MOVES-based emission factors;
- Updating to the improved estimate of the average trip length for drayage trucks; and
- Simplifying the emissions calculation methodology to account for strictly the onroad emissions that occur outside of the NYNJLINA nonattainment area.

The Port Authority commissions two drayage truck emission assessments, one conducted by Starcrest Consulting for the Ports department, and the other conducted by SC&A for OEEP. To ensure consistency between these two independent assessments, SC&A uses the Starcrest-derived emissions total for drayage trucks. Therefore, estimates for truck travel on the port terminals, truck idling, and travel from the terminals up to the point of the nonattainment border (the boundary of the Starcrest emissions inventory) were obtained from the 2006 Starcrest report. SC&A builds upon this estimate to assess drayage truck emissions from the nonattainment area boundary to the first point of rest (as is typical in GHG inventories), up to a maximum of 400 miles.

Thus, in revising the 2006 Ports attracted travel emissions to account for MOVES-based emission factors and to maintain a consistent analysis approach across analysis years, SC&A updated the estimates of onroad drayage truck emissions from the nonattainment area boundary to the first point of rest. We accounted for these emissions using data and assumptions consistent with those used in the Starcrest drayage truck emission inventory calculations.

Emissions from the portion of the drayage truck trips that extend from the nonattainment area boundary to the first point of rest are calculated as the product of three data components. These are: 1) the number of drayage truck trips to the container terminals, 2) the average drayage truck trip distance outside of the nonattainment area to the first point of rest, and 3) a MOVES-based CO<sub>2</sub>e emission factor representative of onroad drayage truck travel.

Drayage Truck Trips to Container Terminals. The number of 2006 drayage truck trips to container terminals is provided in the 2006 Starcrest report.

Drayage Truck Trip Distance Outside of Nonattainment Area. For the 2012 GHG inventory report, SC&A had estimated the total trip length of port drayage trucks to be 46.4 miles one way, using a methodology that made improvements upon the estimate originally used in the 2006 GHG inventory. We use Starcrest data to determine the portion of this average trip distance that occurs within the nonattainment area. The Starcrest reports do not separately itemize the average onroad trip length traveled by drayage trucks servicing the container terminals. However, these reports provide the number of drayage truck trips to the container terminals and the total off-terminal VMT of these trucks within the nonattainment area. We estimated the average VMT per container truck trip by dividing the total VMT of these trucks by the total number of the drayage truck trips to the container terminals which resulted in an average per-trip estimate of 32.7 miles (roundtrip) in 2006 within the nonattainment area. Thus, the total average mileage traveled by a truck servicing the container terminals from the nonattainment area boundary to the first point of rest would be 60.1 miles (46.4 miles/one-way to First Point of Rest \* 2 one-way/roundtrip – 32.7 miles/roundtrip Non-Attainment Area = 60.1 miles/roundtrip Incremental from Non-Attainment Area) in 2006. Both the SC&A trip distance and the data underlying Starcrest's VMT estimate were based on data from the Port Authority Marine Container Terminals Truck Origin/Destination Survey 2005 prepared by Vollmer which has not been updated since that time. Total VMT outside the nonattainment area to the first point of rest was calculated by multiplying the trip length outside the nonattainment area by the number of container truck trips.

MOVES CO<sub>2</sub>e Emission Factor. The 2006 Starcrest report used MOBILE6 emission factors in calculating drayage truck emissions. As with the other attracted travel categories, SC&A used the latest version of the MOVES model to estimate a 2006 CO<sub>2</sub>e emission factor applicable to drayage trucks.

Table D-1 summarizes the resulting data components in 2006. This table also shows the emissions for the portion of drayage truck trips between the nonattainment area boundary and the first point of rest, calculated as the product of the three data components listed in Table D-1. These emissions should then be added to the port commerce truck emissions reported in the 2006 Starcrest report to obtain the total port commerce attracted travel emissions from heavy-duty trucks.

<b>Table D-1. Data Components for Drayage Trucks from the Nonattainment to First Point of Rest Boundary</b>	
<b>Data Component</b>	<b>2006</b>
Number of Truck Trips to Container Terminals	3,062,660
VMT by Container Trucks Outside of Nonattainment Area (mi)	60.1
MOVES-based CO <sub>2</sub> e Onroad Emission Factor for Drayage Trucks (g/mi)	2,176
Drayage Truck CO <sub>2</sub> e Emissions from Nonattainment Area to First Point of Rest (metric tons)	400,173

It should be noted that the 2006 inventory does not include emissions associated with drayage truck travel to the Global Marine Terminal, as the Port Authority did not own that terminal in 2006. Emissions associated with this terminal are included in other analysis years.

### 3. Other Methodologies

#### 3.1. Fugitive Emissions, Refrigerants

The initial base year only had a partial assessment and many data points were incongruent with later inventories known to have higher quality activity data. From EY2010 to EY2014, the inventory program made a strong push to have a full picture of refrigerant emissions by inventorying air conditioning (AC) equipment and their key characteristics, such as refrigerant type, charge, and cooling capacity. So, for the revised base year, the value from the 2012 to 2014 period that met the following two conditions was selected: a) the value was derived from a refrigerant survey, and b) the utilization coefficient was less than a full year, since AC equipment only runs in the warm season.

Application of this method resulted in the revision of all entries in the Scopes Table associated with the “Refrigerant and Fire Suppressants” activity, except for Ports NJMT, for which the original estimate was in line with subsequent years.

#### 3.2. Energy Production, Essex County Resource Recovery Facility

The initial base year was calculated as a function of waste tonnage and a national profile of waste composition, yielding a low confidence assessment. For the revised base year, we tapped on GHG data collected by EPA per 40 CFR Part 98 since 2010, and supplemented that information with GHG and CAP data as retrieved from eGRID for 2007 to recreate an 8-year data series; note the eGRID library does not have 2006 data. SC&A performed a trend analysis and observed that plant emissions fell within a band. To fill in for 2006, SC&A assigned the median value of the 8-year period for each pollutant. For instance, biogenic CO<sub>2</sub> ranged from 368 kilotons to 530 kilotons, of which the median value was 381 kilotons.

Application of this method resulted in the revision of Energy Production emissions in the Scopes Table associated with the “Essex County Resource Recovery facility” short facility name.

#### 3.3. Biogenic Emissions - Central Automotive Division, Employee Commuting, Elizabeth Landfill

The 2006 GHG inventory did not estimate biogenic emissions. For all three of these categories, biogenic emissions are estimated based on the 2006 estimate of anthropogenic emissions. For all three categories, the first year where biogenic emissions were estimated was used to establish a ratio of biogenic emissions to anthropogenic emissions for each category. For the Central Automotive division, 2010 was used for the ratio, and for Employee Commuting and Elizabeth Landfill, 2013. This ratio was then applied to the 2006 estimate of anthropogenic emissions to estimate biogenic emissions in 2006.

#### 3.4. Aircraft Emissions – Aircraft Movements

2006 Aircraft emissions were initially estimated using IPCC emission factors, which are very conservative and may potentially overestimate emissions. This analysis instead re-estimates these aircraft using the FAA’s EDMS model (version 5.1.3), which was the standard tool for estimating aircraft emissions until it was replaced by the AEDT model. The 2006 aircraft list was converted into EDMS inputs using each aircraft’s IPCC aircraft code. These aircraft totals were then normalized to match the FAA’s ATADS database of total flights occurring at each airport in

2006 (as is done in all aircraft inventories from 2011 forward). EDMS then provides an emissions estimate of CO<sub>2</sub> and the CAPs. CH<sub>4</sub> and N<sub>2</sub>O emissions were estimated in post processing based on the IPCC kg/LTO emission factors. For aircraft with no IPCC emission factors available, a weighted emission factor of kg/LTO was applied for each airport.

### 3.5. Aircraft Emissions – Ground Support Equipment

Ground Support Equipment (GSE) was not estimated in the initial 2006 inventory. There is no GSE equipment inventory available for 2006, so instead emissions are estimated based on the default assignment of GSE based on aircraft type in EDMS. This provides an estimate of CAP emissions from GSE, but not GHGs. To estimate CO<sub>2</sub> emissions, first we calculated a ratio of diesel and gasoline GSE for each airport from EDMS. Then CO<sub>2</sub> emissions from gasoline and diesel were estimated based on stoichiometry (that is the ratio between gasoline/diesel SO<sub>2</sub> and gasoline/diesel CO<sub>2</sub> emissions). Then CH<sub>4</sub> and N<sub>2</sub>O emissions were estimated using the ratio of CO<sub>2</sub> to CH<sub>4</sub>/N<sub>2</sub>O emissions seen in aircraft emissions.

### 3.6. Aircraft Emissions – APUs

Auxiliary Power Units (APUs) were not estimated in the initial 2006 inventory. There is no available information on APU units in 2006, so instead emissions are estimated based on the default assignment of APUs based on aircraft type in EDMS. This provides an estimate of CAP emissions from APUs, but not GHGs. To estimate CO<sub>2</sub> emissions, we use the ratio of SO<sub>2</sub> to CO<sub>2</sub> emissions seen in aircraft emissions multiplied by the SO<sub>2</sub> emissions from APUs. Then CH<sub>4</sub> and N<sub>2</sub>O emissions were estimated using the ratio of CO<sub>2</sub> to CH<sub>4</sub>/N<sub>2</sub>O emissions seen in aircraft emissions. No adjustments were made for Ground Power Units or Pre-conditioned air at any of the airports, because we do not have information about when these units were installed at each airport.

### 3.7. Filling in Missing Data from the 2006 Dataset

Many emissions categories were omitted from the 2006 inventory that need to be included. In many cases, there is not sufficient data to re-estimate emissions for these categories, so instead a later analysis year is used to fill in these missing emissions. Table D-2 below shows the emissions categories that were filled in with the first available analysis year.

Table D-2. List of Sources Added to the Revised EY2006 Inventory				
Department	Emission Category	Scope	Activity	Facility Name
Aviation	Stationary Combustion	1	Buildings	Teterboro Airport
Aviation	Purchased Electricity	2	Buildings	Teterboro Airport
Aviation	Stationary Combustion	3	Buildings	AirTrain JFK
Aviation	Stationary Combustion	3	Buildings	John F. Kennedy International Airport

Tunnels, Bridges & Bus Terminals	Purchased Steam	2	Buildings	Bus Terminals
Tunnels, Bridges & Bus Terminals	Purchased Electricity	2	Buildings	Bus Terminals

### 3.8. Filling in Questionable Data from the 2006 Dataset

There were also some emissions categories that had an emissions estimate in 2006 that is not in line with later estimates. We believe these estimates are not accurate and are most likely the result of incomplete data or different assumptions in the 2006 analysis. The first historical estimate where emissions are in line with later estimates was used to fill in the 2006 estimate. Table D-3 shows the emissions categories where the 2006 estimate was replaced with an estimate from a later year.

<b>Table D-3. List of EY2006 Sources Aligned to the Historical Emissions Trend</b>				
<b>Scope</b>	<b>Department</b>	<b>Emission Category</b>	<b>Activity</b>	<b>Facility Name</b>
1	Aviation	Stationary Combustion	Buildings	Newark Liberty International Airport
2	Aviation	Purchased Electricity	Buildings	John F. Kennedy International Airport
3	Aviation	Purchased Electricity	Buildings	John F. Kennedy International Airport
3	Aviation	Stationary Combustion	Buildings	Newark Liberty International Airport
3	Aviation	Purchased Electricity	Buildings	Newark Liberty International Airport
3	Aviation	Stationary Combustion	Buildings	Teterboro Airport
3	Aviation	Purchased Electricity	Buildings	Teterboro Airport

### 3.9. Mobile Combustion – Ferry Movements

Mr. Amit Bhowmick, General Manager for the Ferry Transportation Program, confirmed that the World Financial Center (WFC) Terminal was operational in 2006. Furthermore, Mr. Bhowmick provided 2006 route information as well as schedule information on each active route. Combined, these data served as input to the 2006 revision.

SC&A reused the 2014 ferry movements analysis spreadsheet, with the following adjustments:

- Replaced 2014 with 2006 route and schedule information
- Maintained the same average engine age as in the 2014 analysis, namely 10.8 years
- Kept all other engine specifications the same as in 2014.

A comparison between 2014 and 2006 show that routes and schedules were virtually identical, except that the Belford-WFC route was not operational in 2006. This is the main reason why 2006 emissions were lower by 5.4% from 2014.

## 3. Results

The overall effect of the 2006 base year revision resulted in a slight increase of scope 1 emissions, a similar decrease in scope 2 emissions, and a more significant increase in scope 3 emissions. The net change across all scoped from the original base year was 63,603 metric tons CO<sub>2</sub>e, or 1.1 percent of the agency's total carbon footprint. Table D-4 shows a complete anthropogenic emissions comparison by scope and department between the original and revised 2006 base year.

Table D-4. Comparison of the Original and Revised 2006 Base Year					
Scope	Department	Original EY 2006	Revised EY 2006	Net Change	Percent Change from Grand Total
1	Aviation	18,316	32,014	13,698	0.2%
